

Visiting Exoplanet Host Stars Using the CHARA Array

Ellyn Baines

Georgia State University

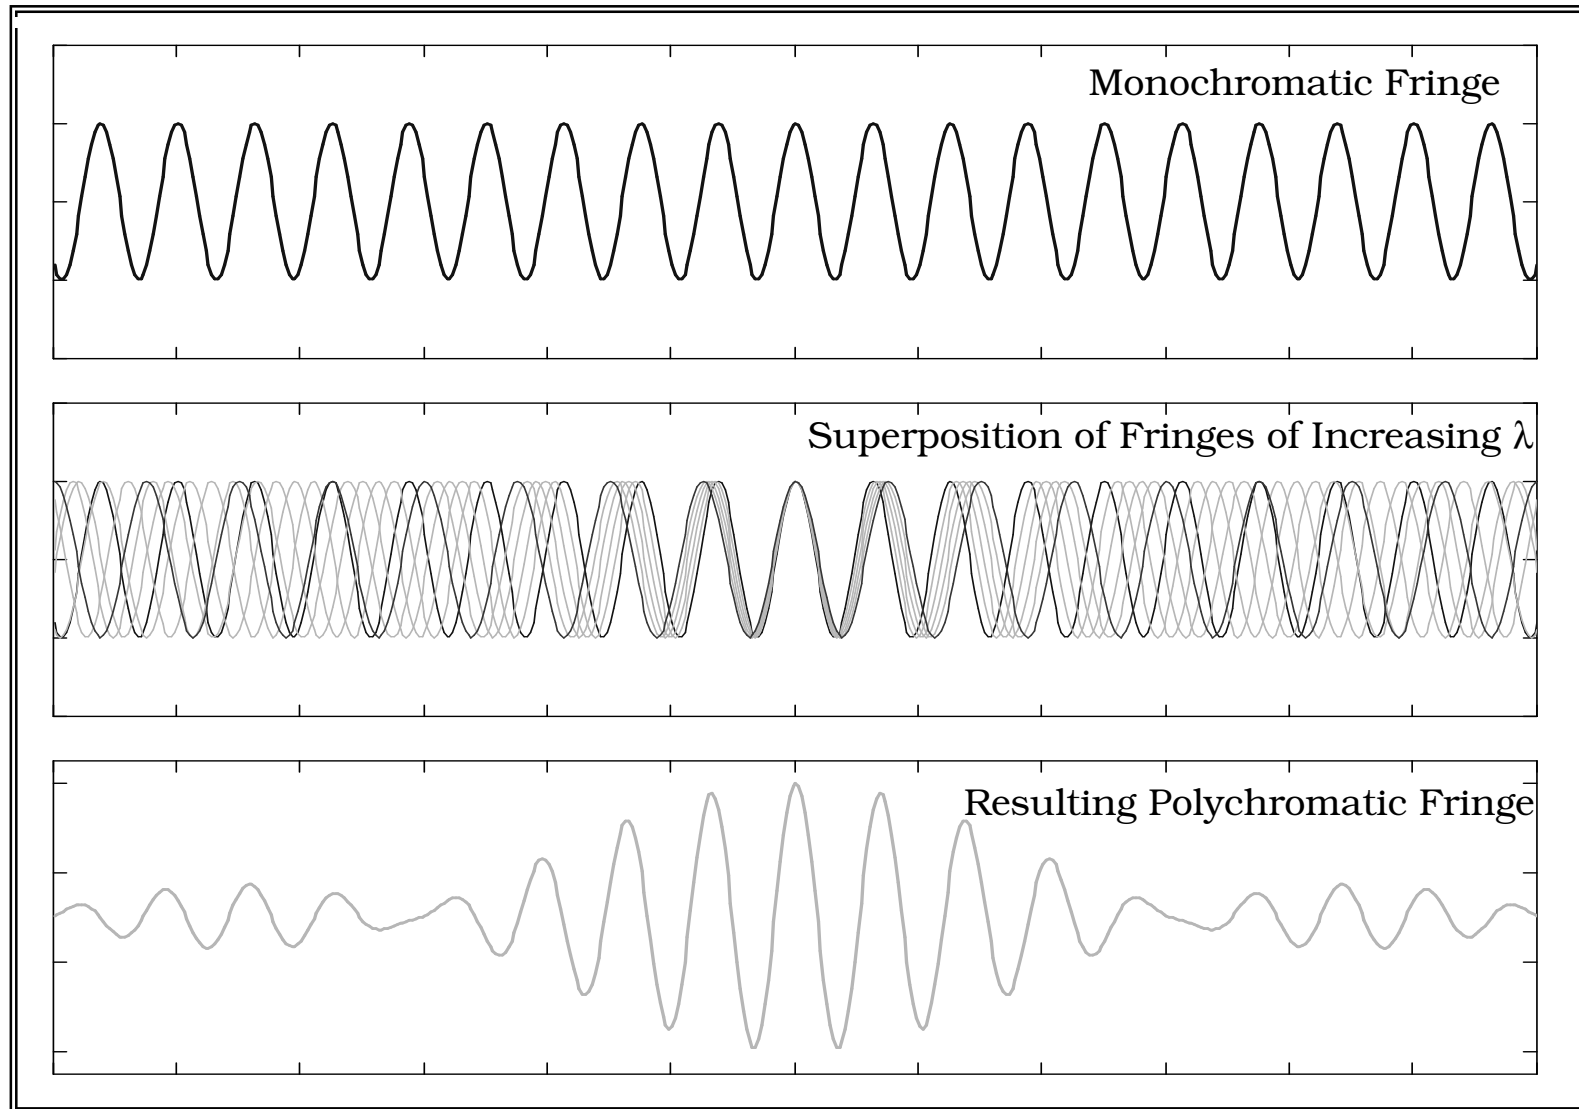

Center for High Angular Resolution Astronomy

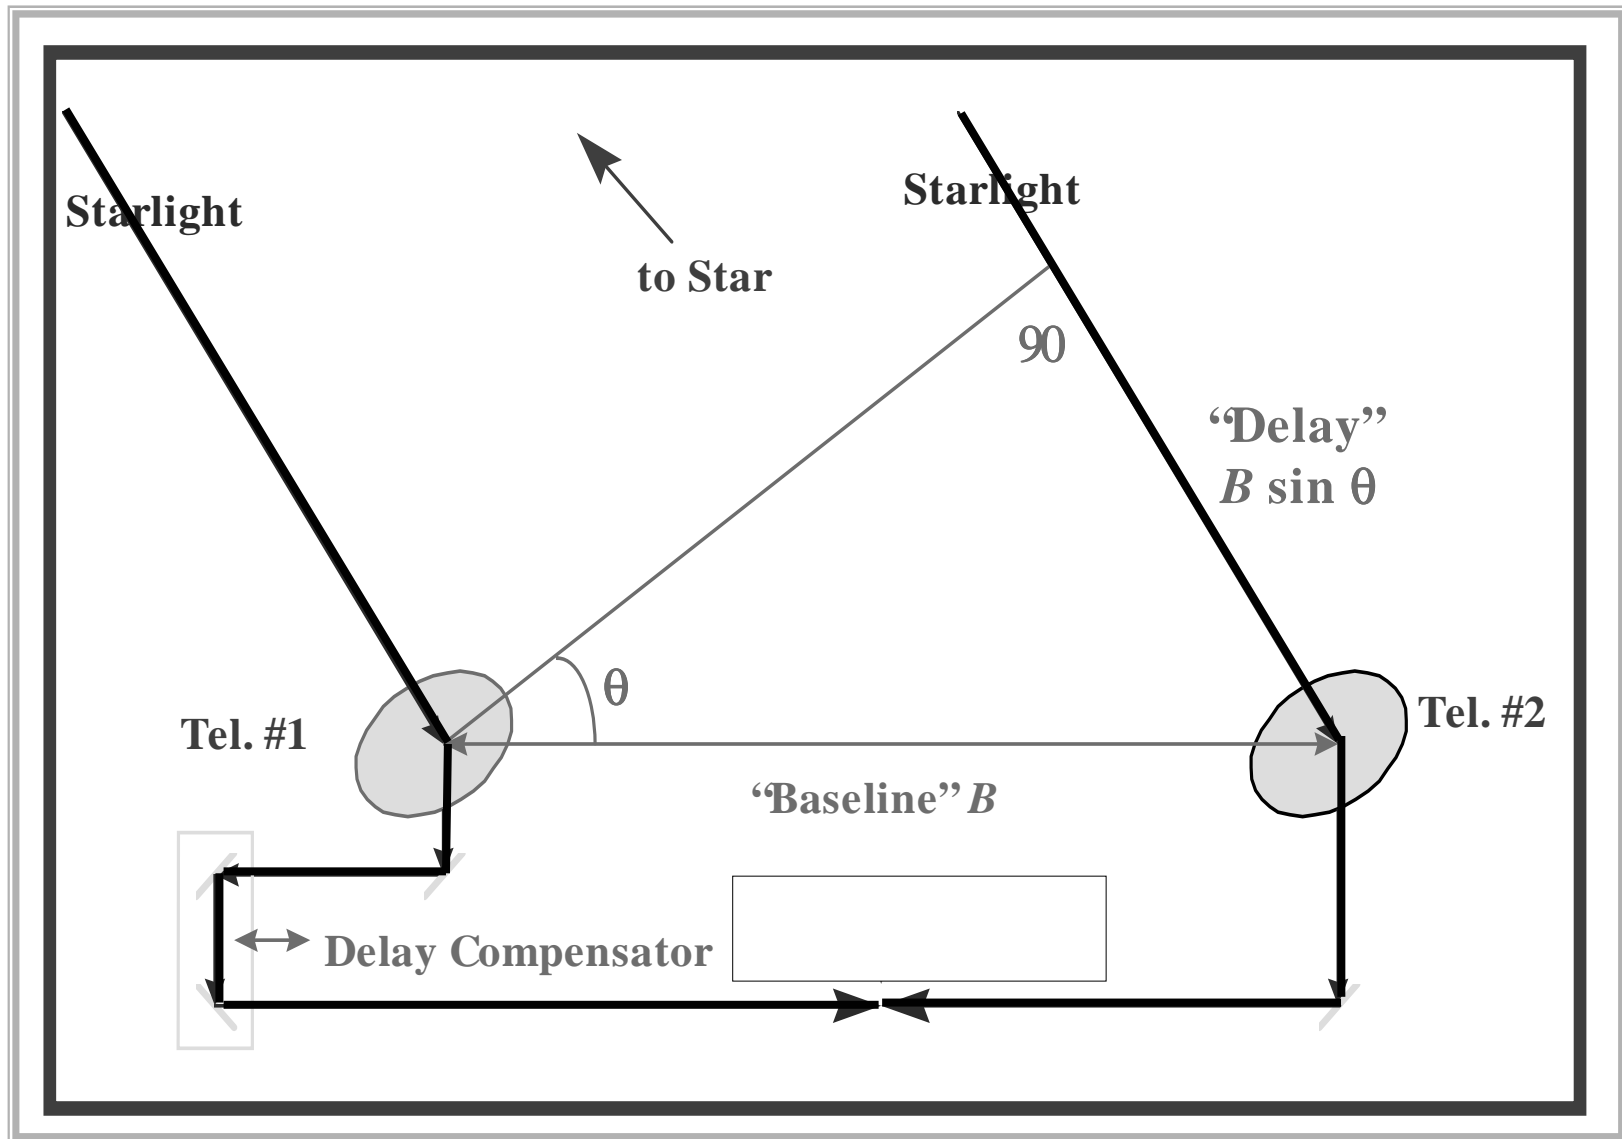

Talk Outline

- Interferometry
- CHARA facilities
- Characterizing exoplanet systems
 - Measure angular diameters
 - Check for stellar companions

Effect of $\Delta\lambda$ on Fringes

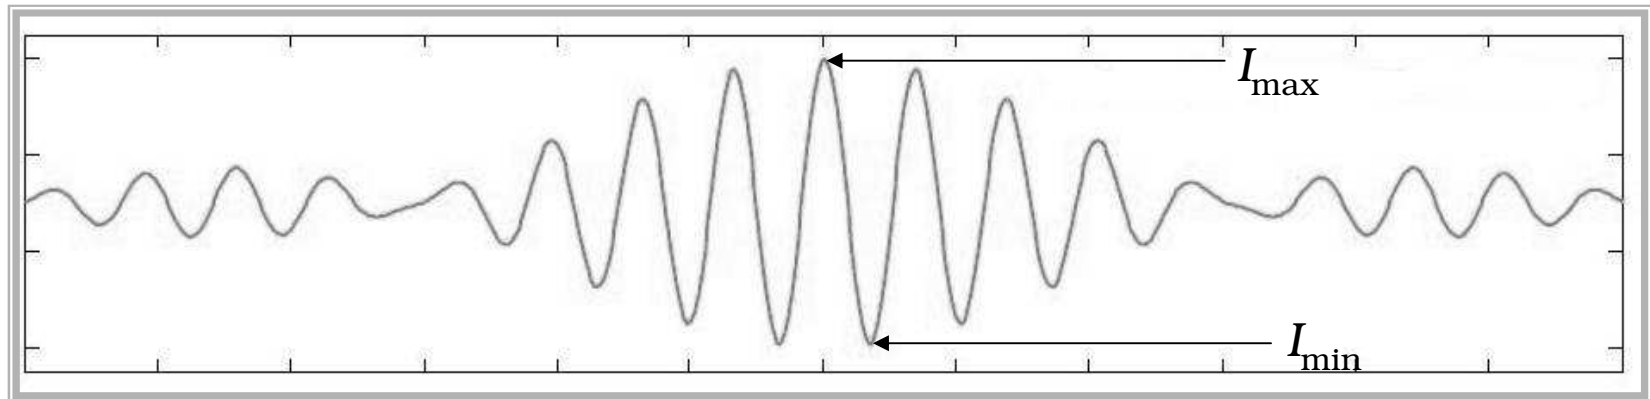

Basic Interferometer

Visibility - Easy

$$V = \frac{I_{\max} - I_{\min}}{I_{\max} + I_{\min}}$$

- $V=0 \rightarrow$ fully resolved
- $V=1 \rightarrow$ completely unresolved

Visibility – Less Easy

$$V^2(b, \Theta, \lambda) = (1 - \beta)^{-2} \{ \beta^2 V_1^2 + V_2^2 + 2\beta V_1 V_2 \cos[2\pi b \lambda^{-1} \rho \cos \psi] \}$$

$$V_{1,2}(b, \Theta, \lambda) = 2[J_1(\pi \Theta_{1,2} b / \lambda)] / (\pi \Theta_{1,2} b / \lambda)$$

b =baseline

β =brightness ratio

ρ =angular separation

J_1 =Bessel function

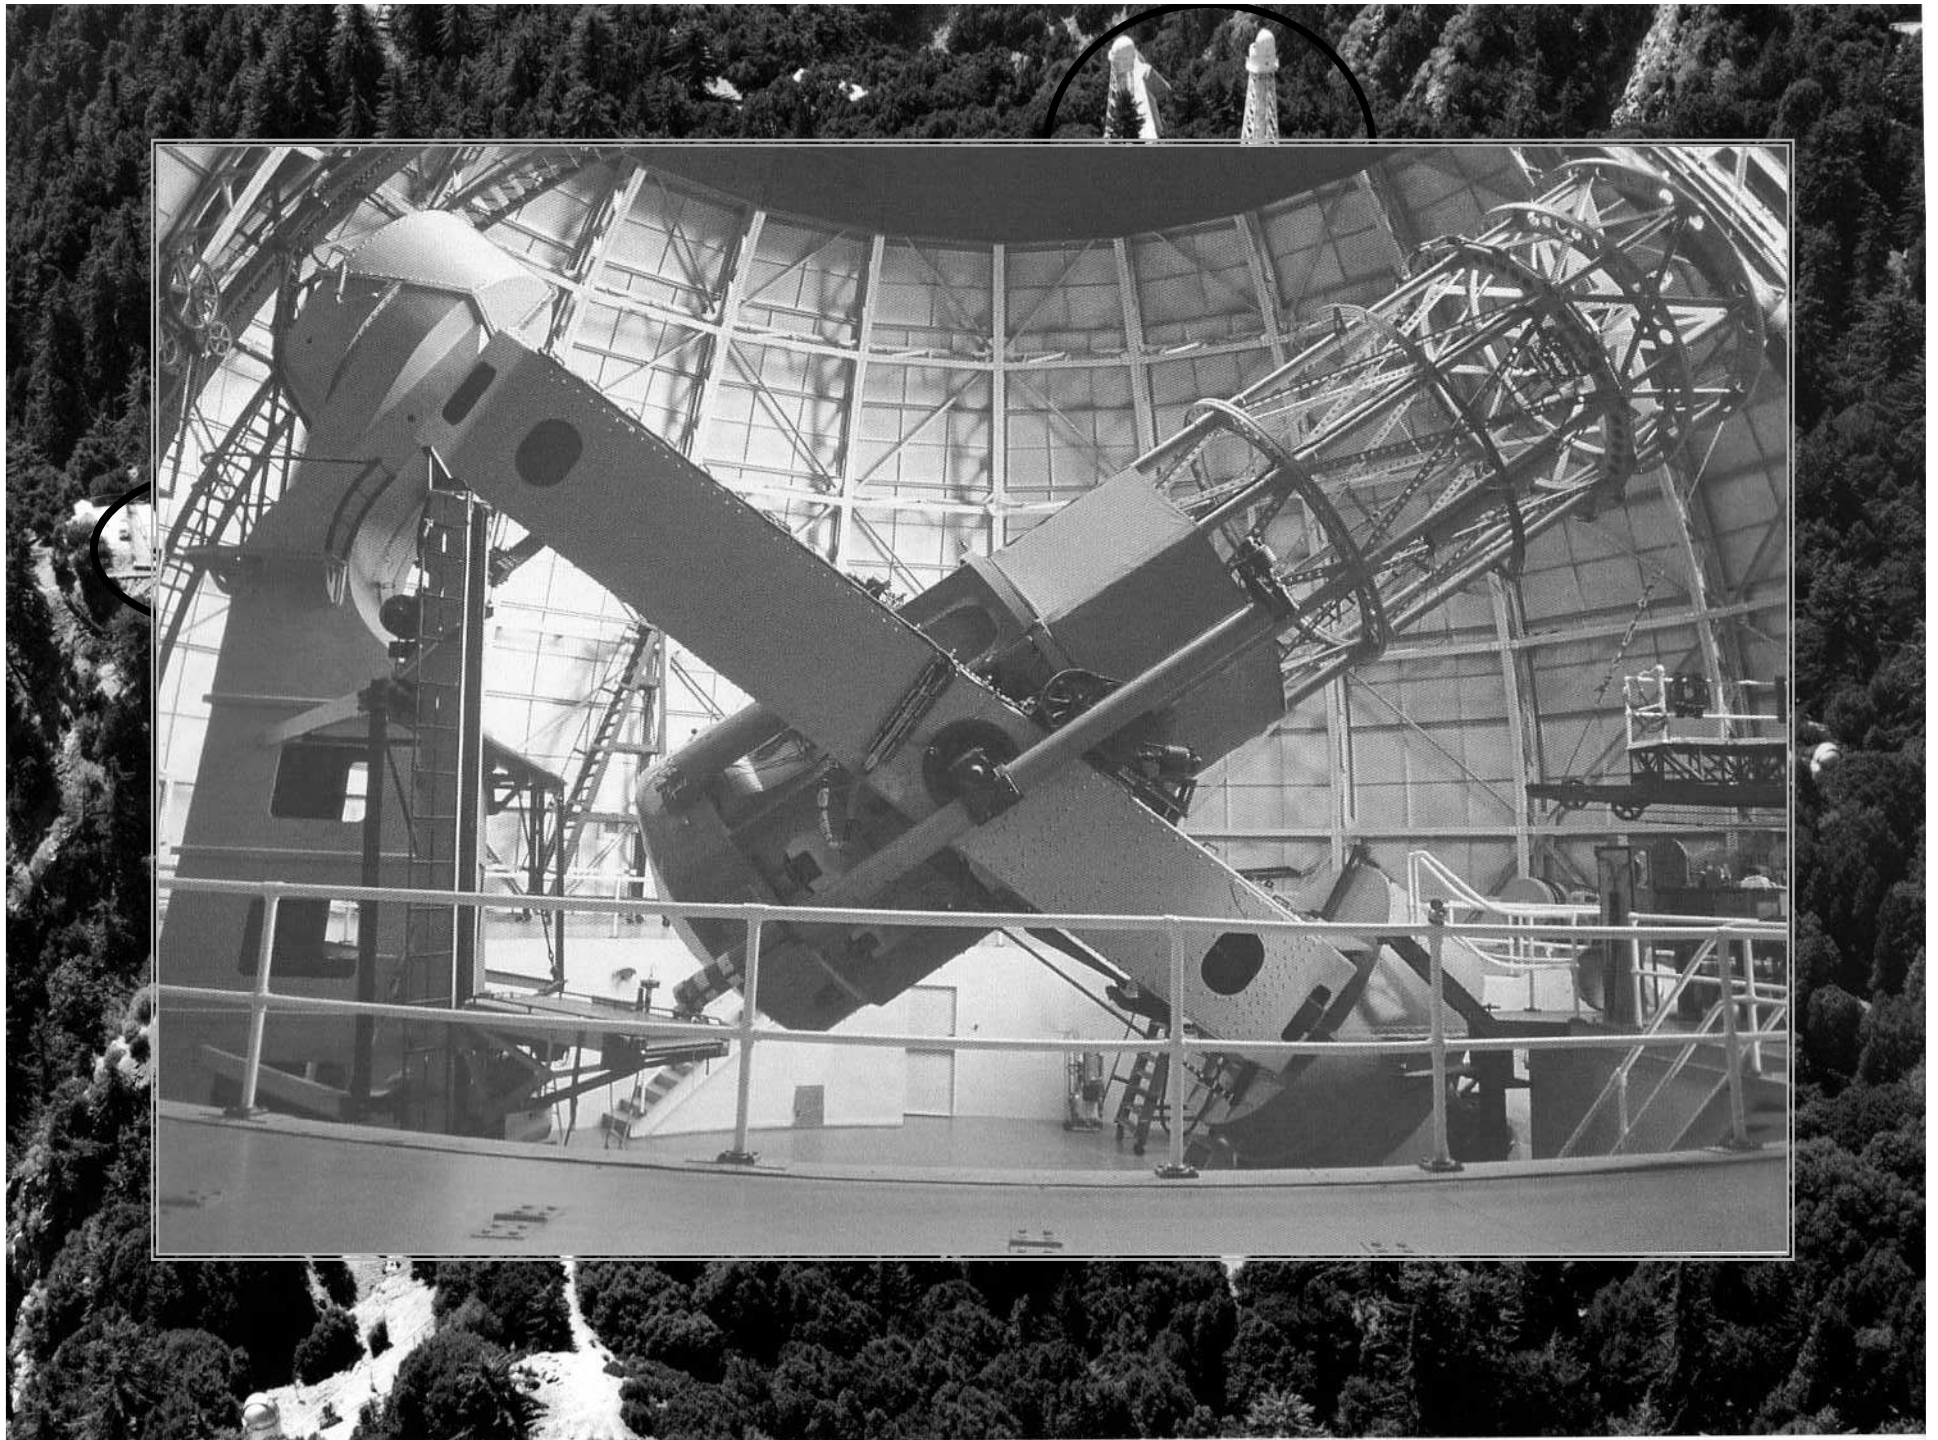

λ =wavelength

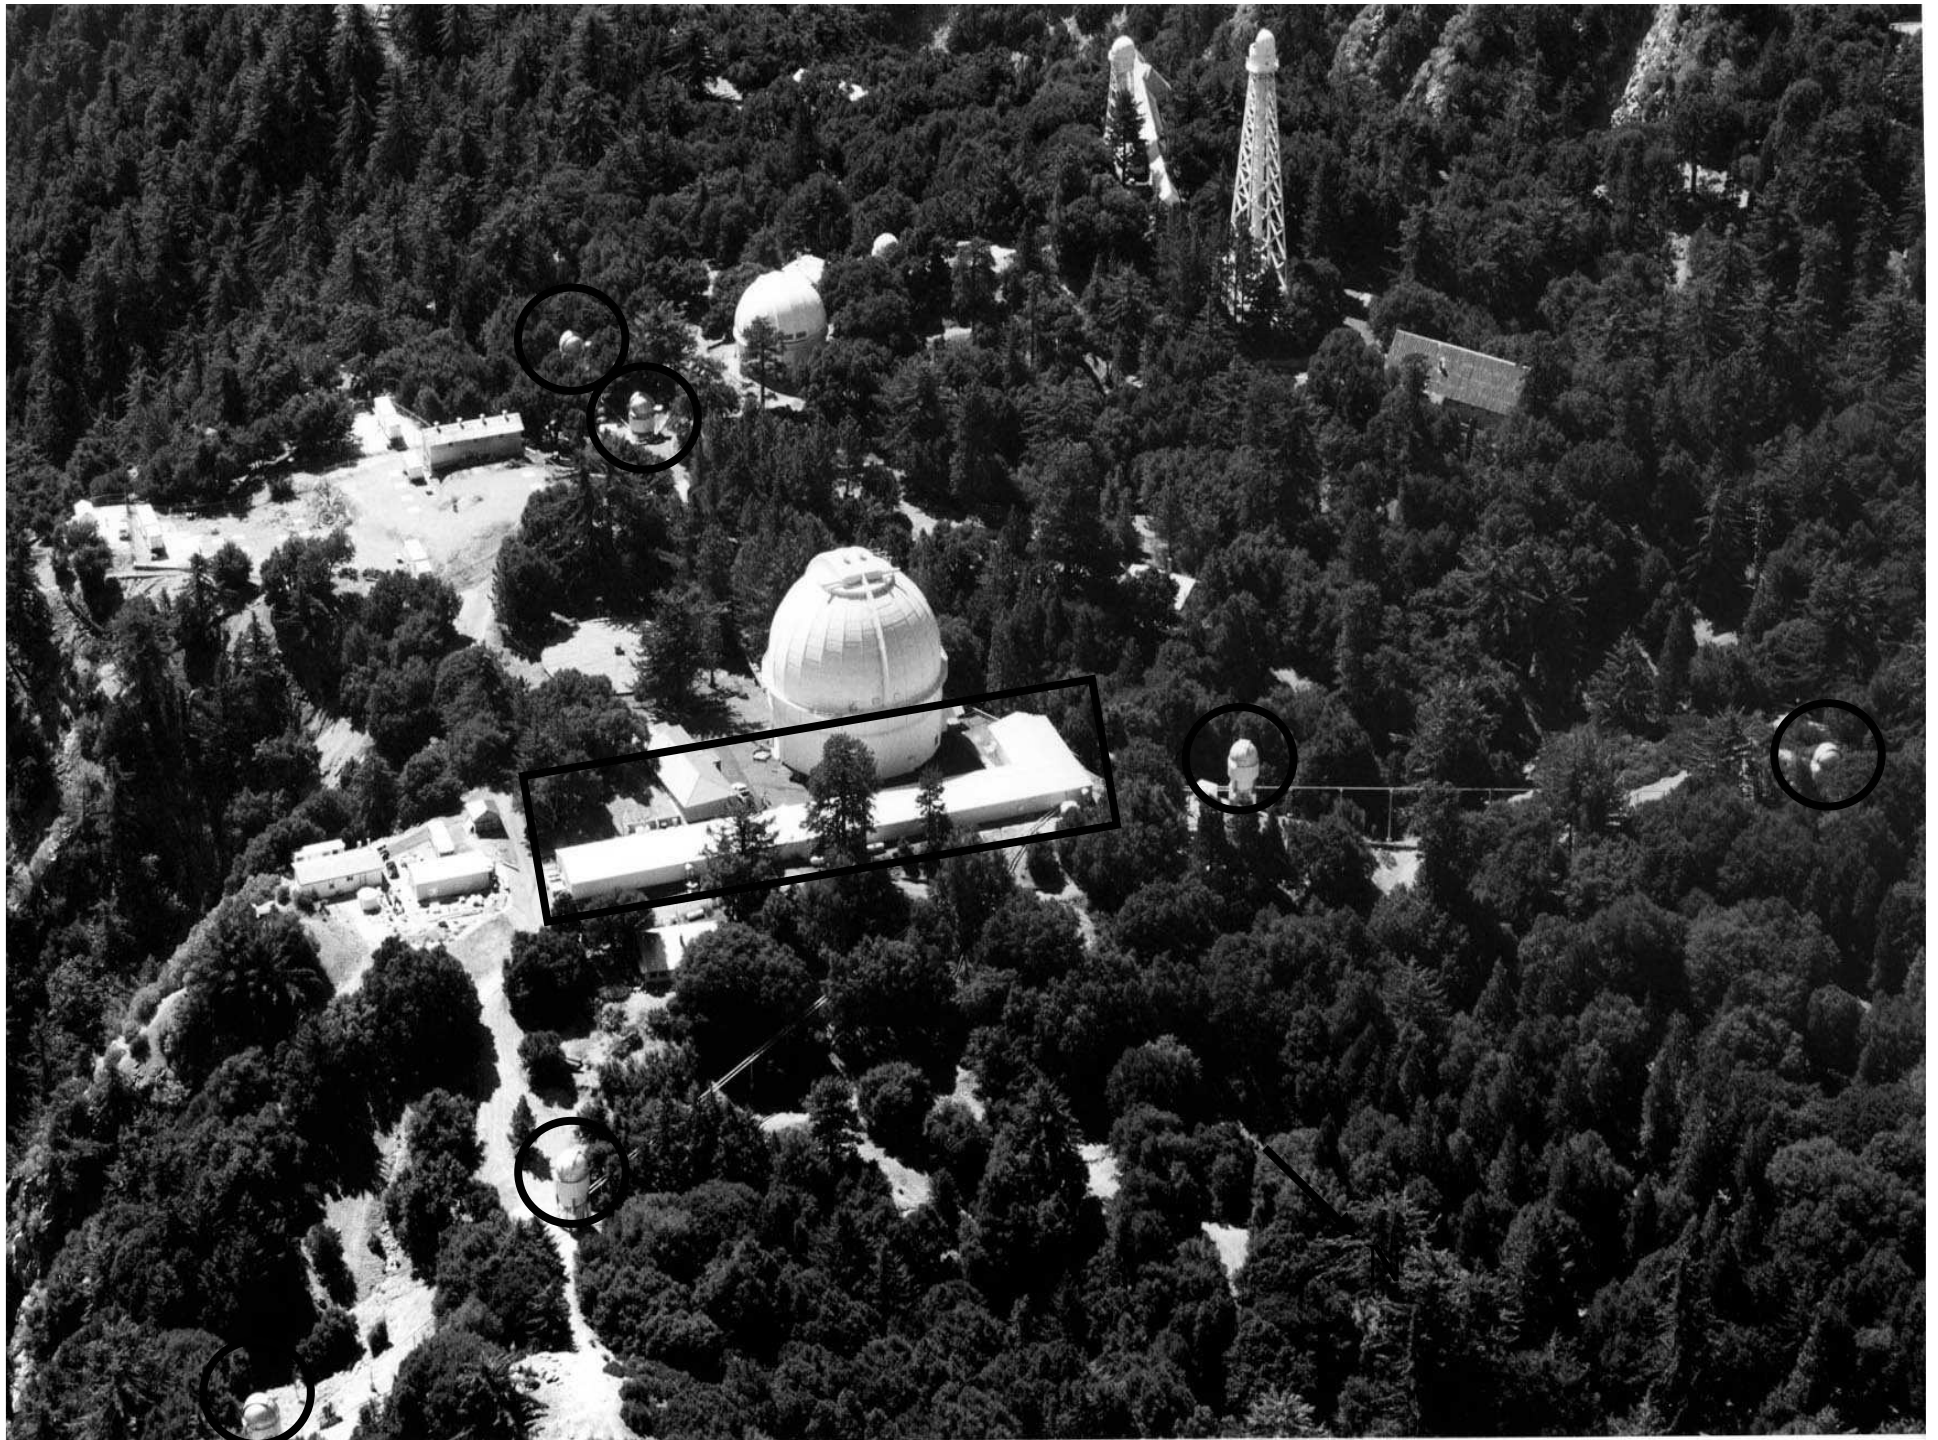

Θ =angular diameter

ψ =difference in position
angle of binary and b

CHARA Array

- Y-shaped configuration of six 1-m scopes
 - 15 baselines from 34 – 331 meters
- Three operating regimes:
 - 470 - 800 nm
 - 2.15 μm
 - 1.65 μm
- Limiting magnitudes:
 - V-band = 9.0
 - K-, H-band = 6.5

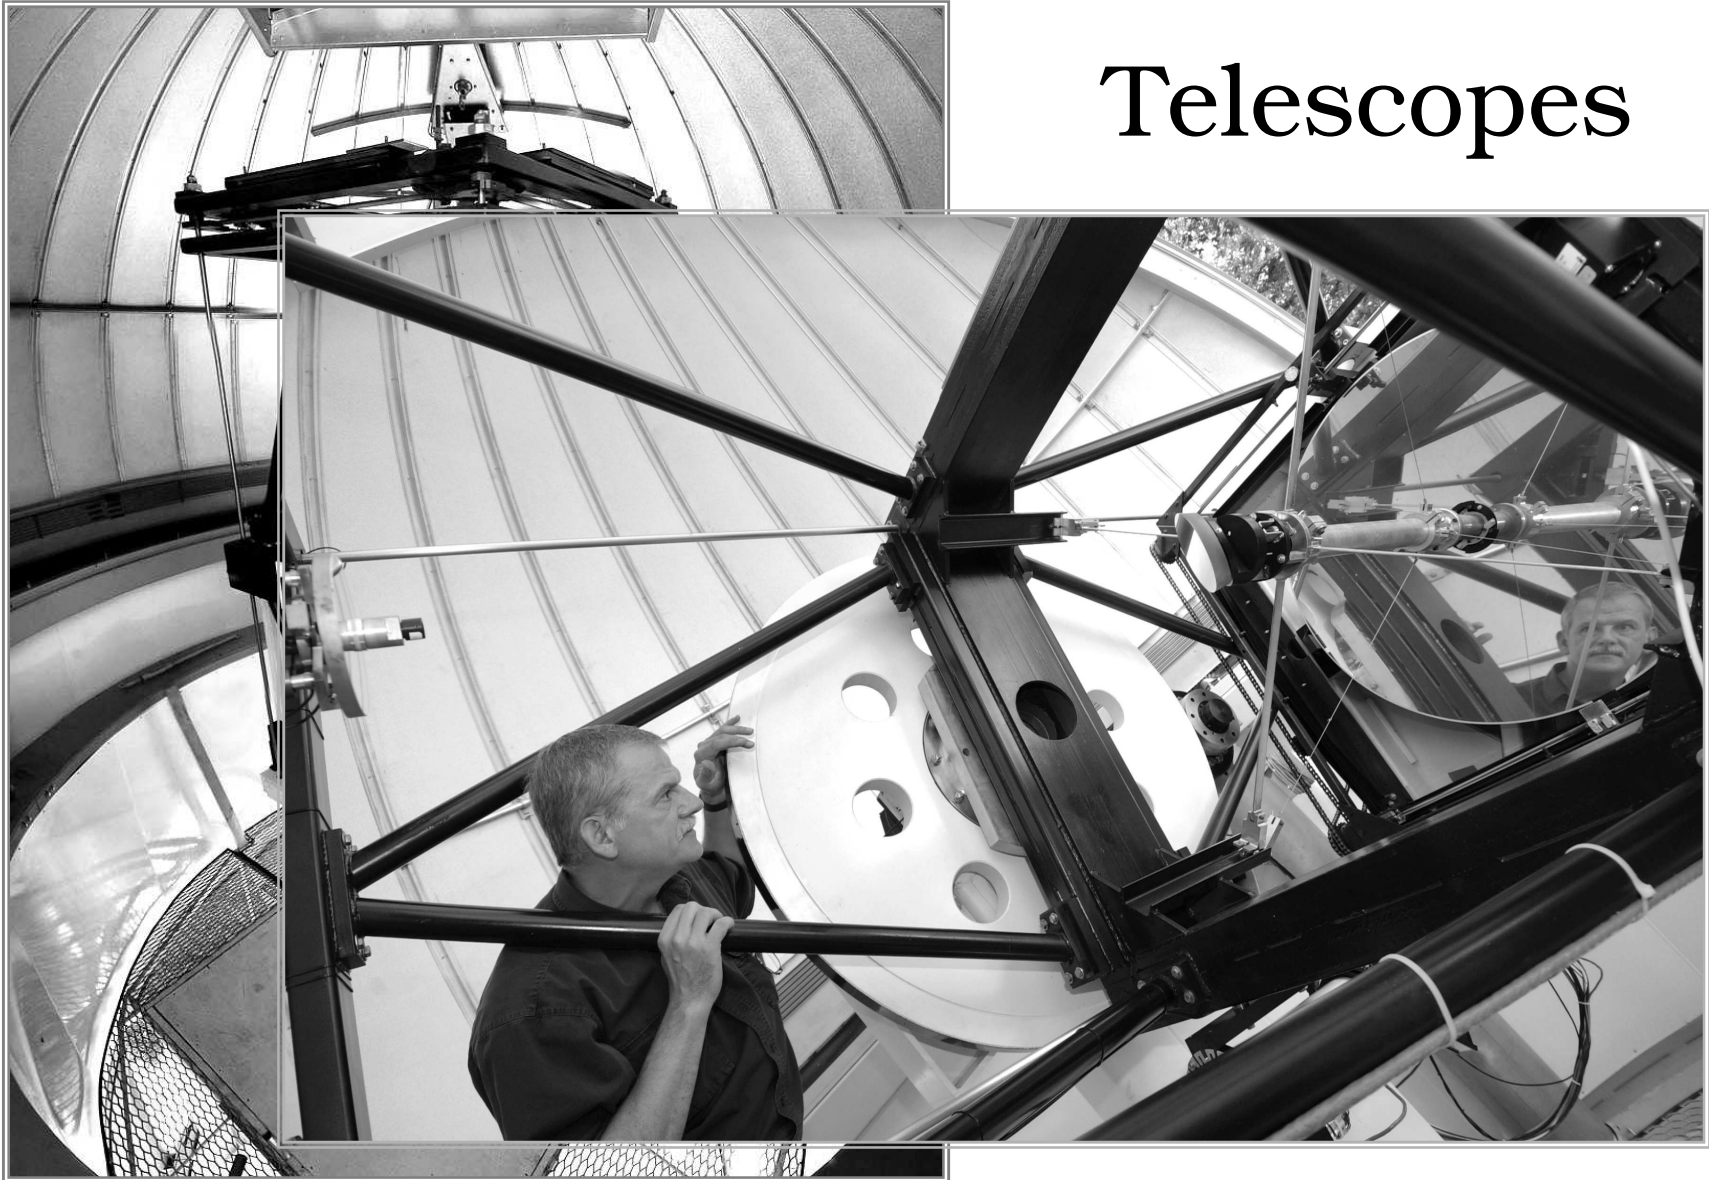

Telescope Enclosures

Telescopes

Vacuum Light Pipes

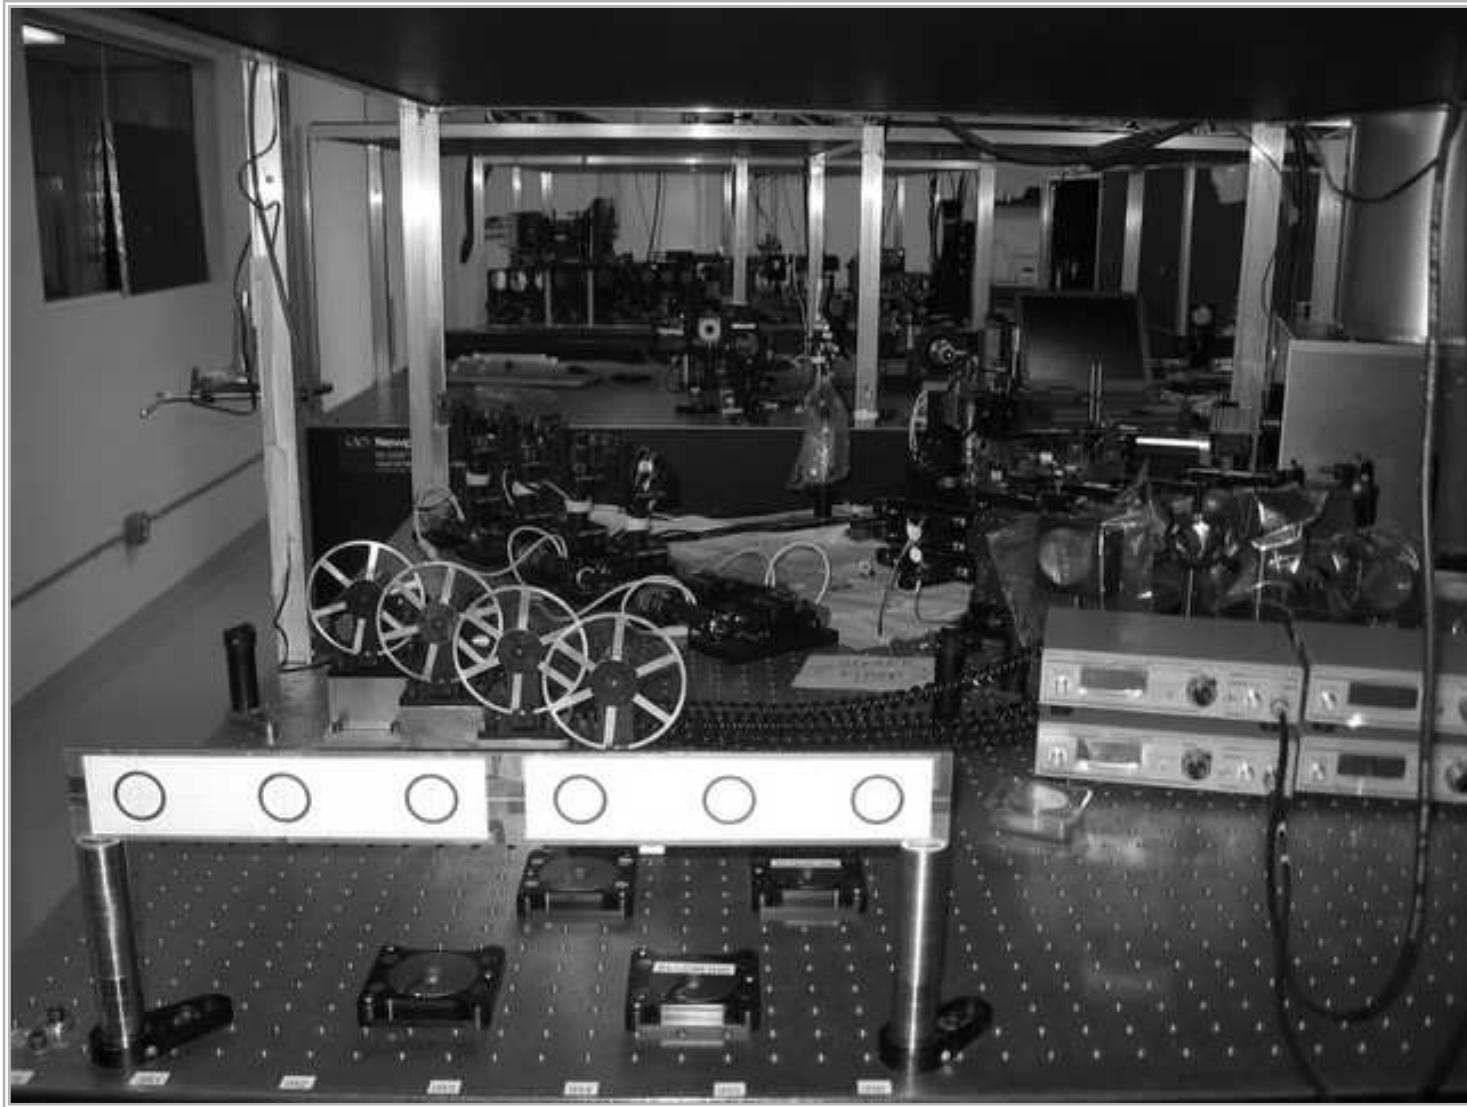

Pipes of Pan

OPLE Carts

Beam Combiner Lab

Remote Operations

CHARA Collaborators

- **CHARA/GSU**
 - Provides faculty, staff & graduate students
 - Directs operations & provides operating budget
- **National Optical Astronomy Observatory** (S. Ridgway)
 - Member of original core design team
- **University of Paris, Meudon** (V. du Foresto)
 - Provides the **FLUOR** 2-way beam combiner for high precision V
- **University of Sydney** (P. Tuthill)
 - Provides southern hemisphere access at SUSI
- **University of Michigan** (J. Monnier)
 - Developing IR fringe tracking and the **MIRC** 4-way beam combiner for closure phase measurements
- **Michelson Science Center, JPL/Caltech**
 - Provides funding for access to observing
- **Observatoire de la Côte d'Azur** (D. Mourard)
 - Visible spectrograph and polarimeter, **VEGA**

Exoplanets

Exoplanets + CHARA

- Characterize host stars
- Measure angular diameters
 - Leads to R_{linear} , M , age
- Check for stellar companions

Previous Estimates

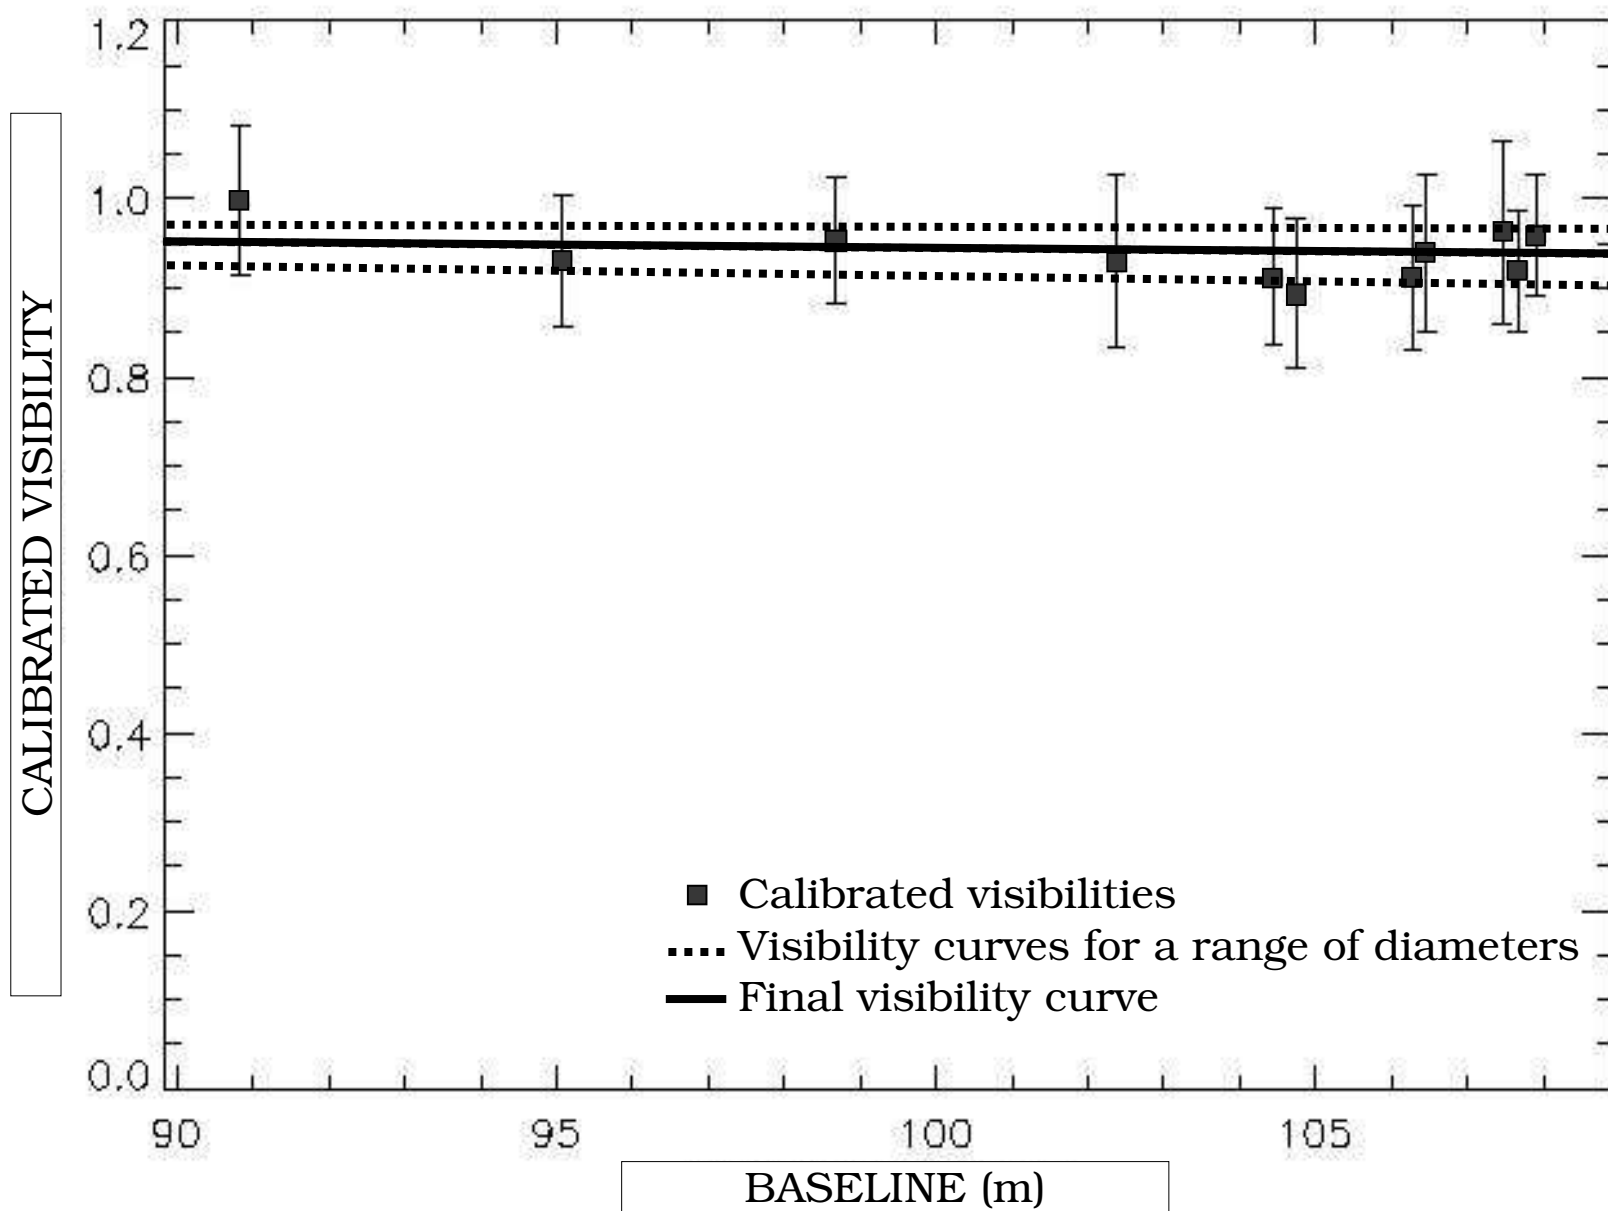

- Ribas et al. (2003):
 - Match 2MASS photometry to synthetic photometry to estimate T_{eff}
 - Use T_{eff} to estimate diameters
- Fischer & Valenti (2005):
 - Estimated radii using luminosities derived from T_{eff} , parallax, and a bolometric correction

Select Calibrators

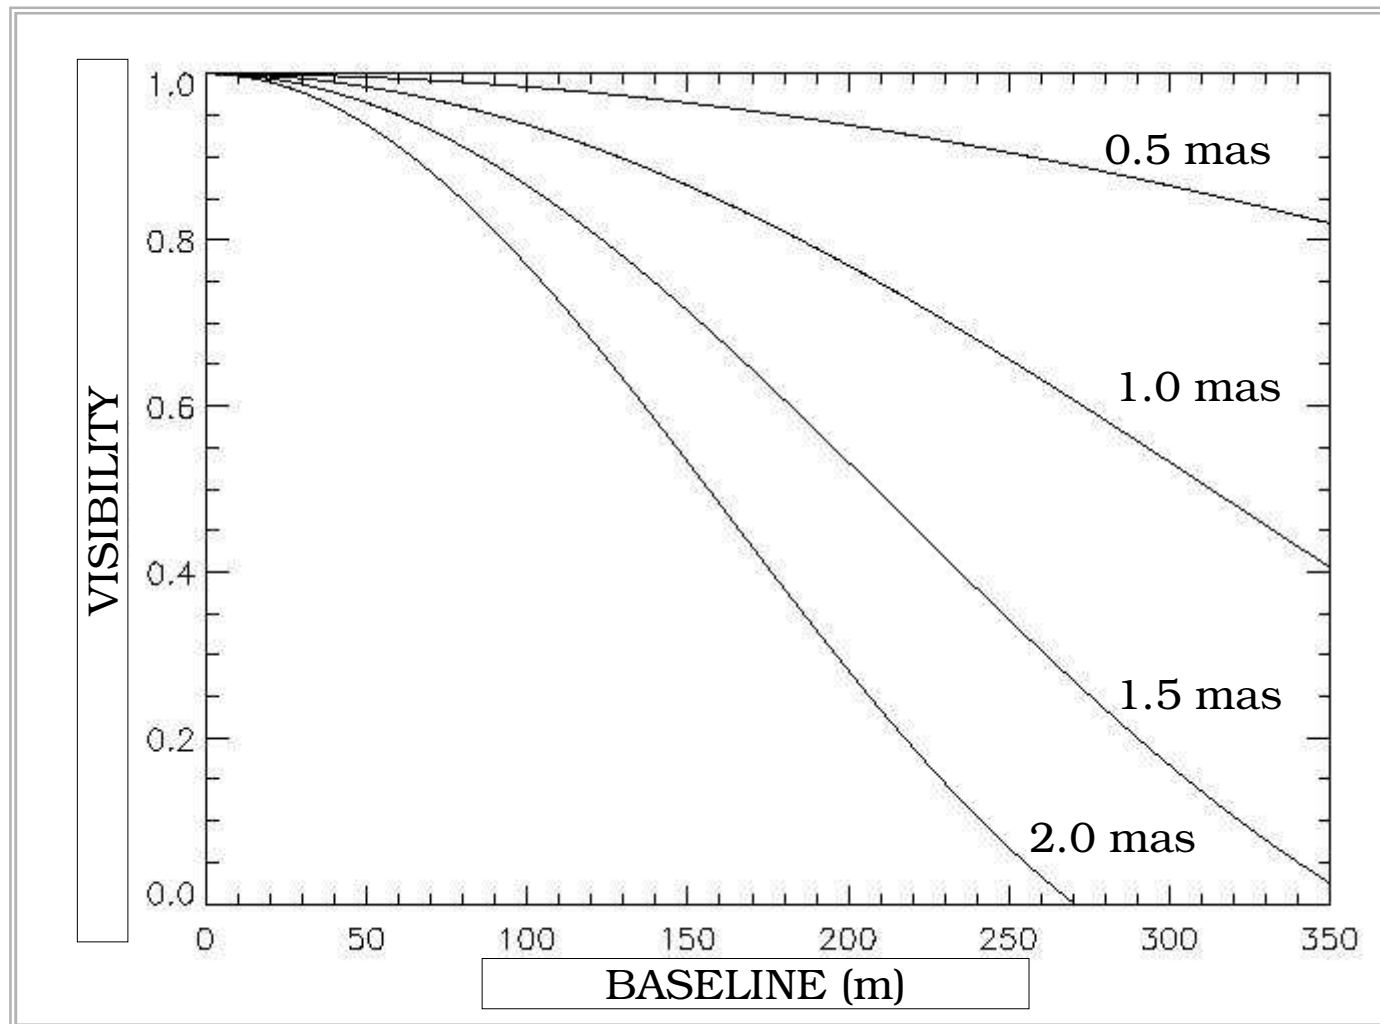

- Single, slowly rotating, boring stars
- Act as the standard to which you measure your target star
- Observe cal – target – cal – target – cal, etc.
- Removes instrumental and seeing effects

Method

- Calibrate target's visibility points
- Fit visibility curves for a range of stellar diameters
- Best fit curve → the corresponding diameter is the answer

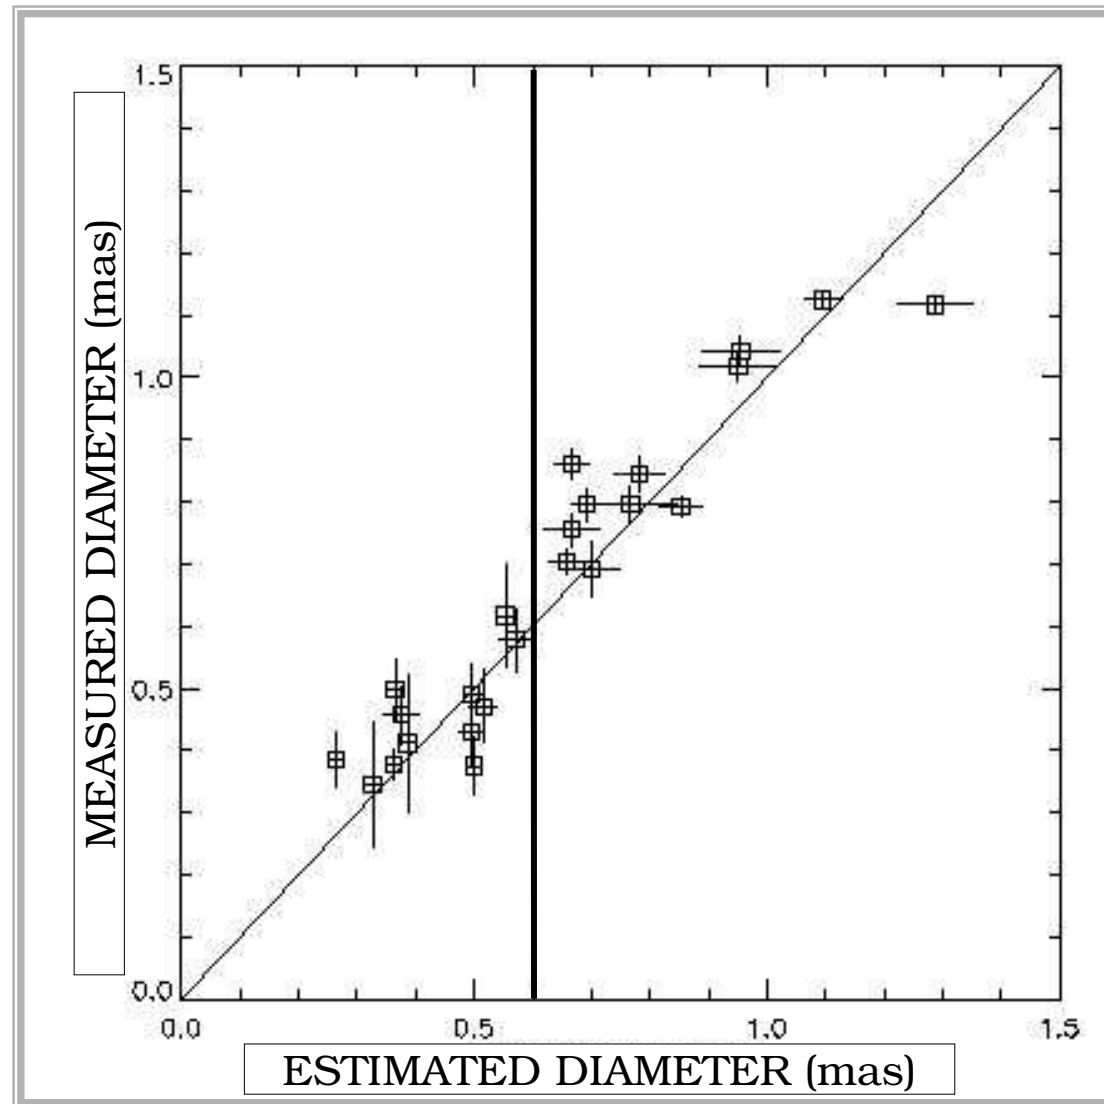

Diameter Effects

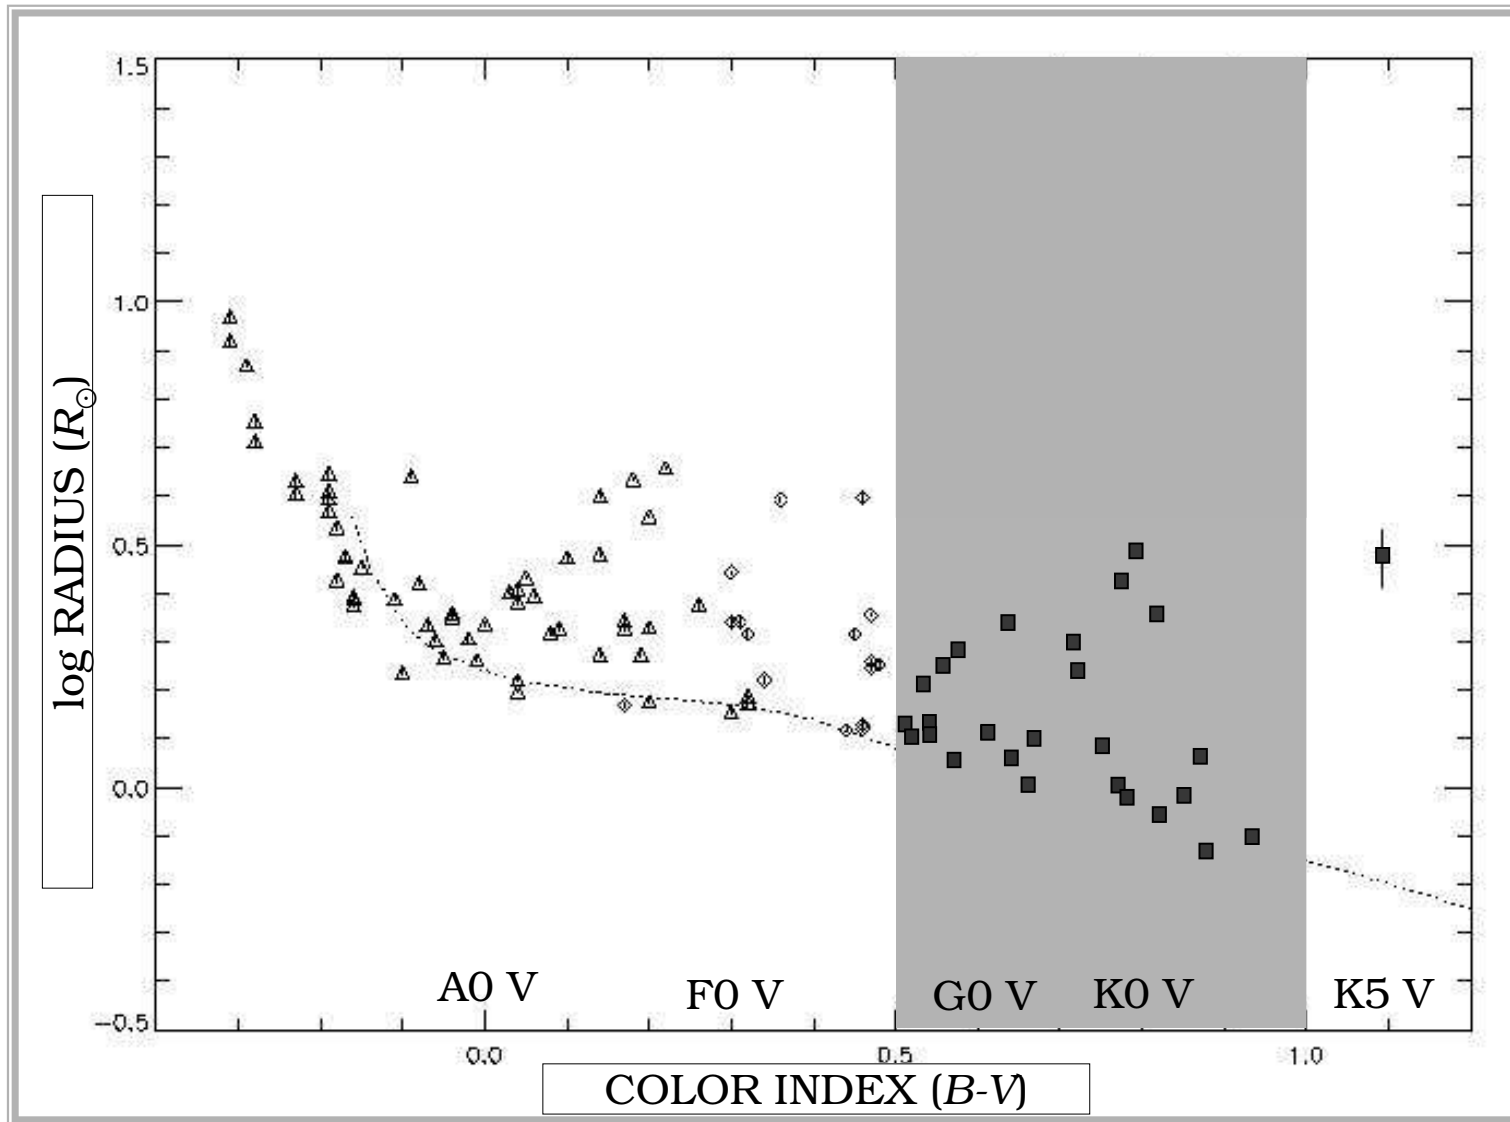

Observations

- Measured 24 host stars
- January 2004 - September 2007
- Stars were chosen by *K* magnitude and declination
- Used *K*-band for all but HD 189733

Measured vs. Estimated Diameters

CHARA + Andersen 1991

Results

- Of the 24 host stars:
 - 3 giants
 - 5 subgiants
 - 11 dwarfs
 - 5 moderately evolved stars
- Many planets orbit *evolving* stars

What do diameters tell us?

- Angular diameter, parallax $\rightarrow R_{\text{linear}}$
- R_{linear} , M , metallicity \rightarrow age

BUT

- Age highly dependent on stellar mass
- Mass not well known

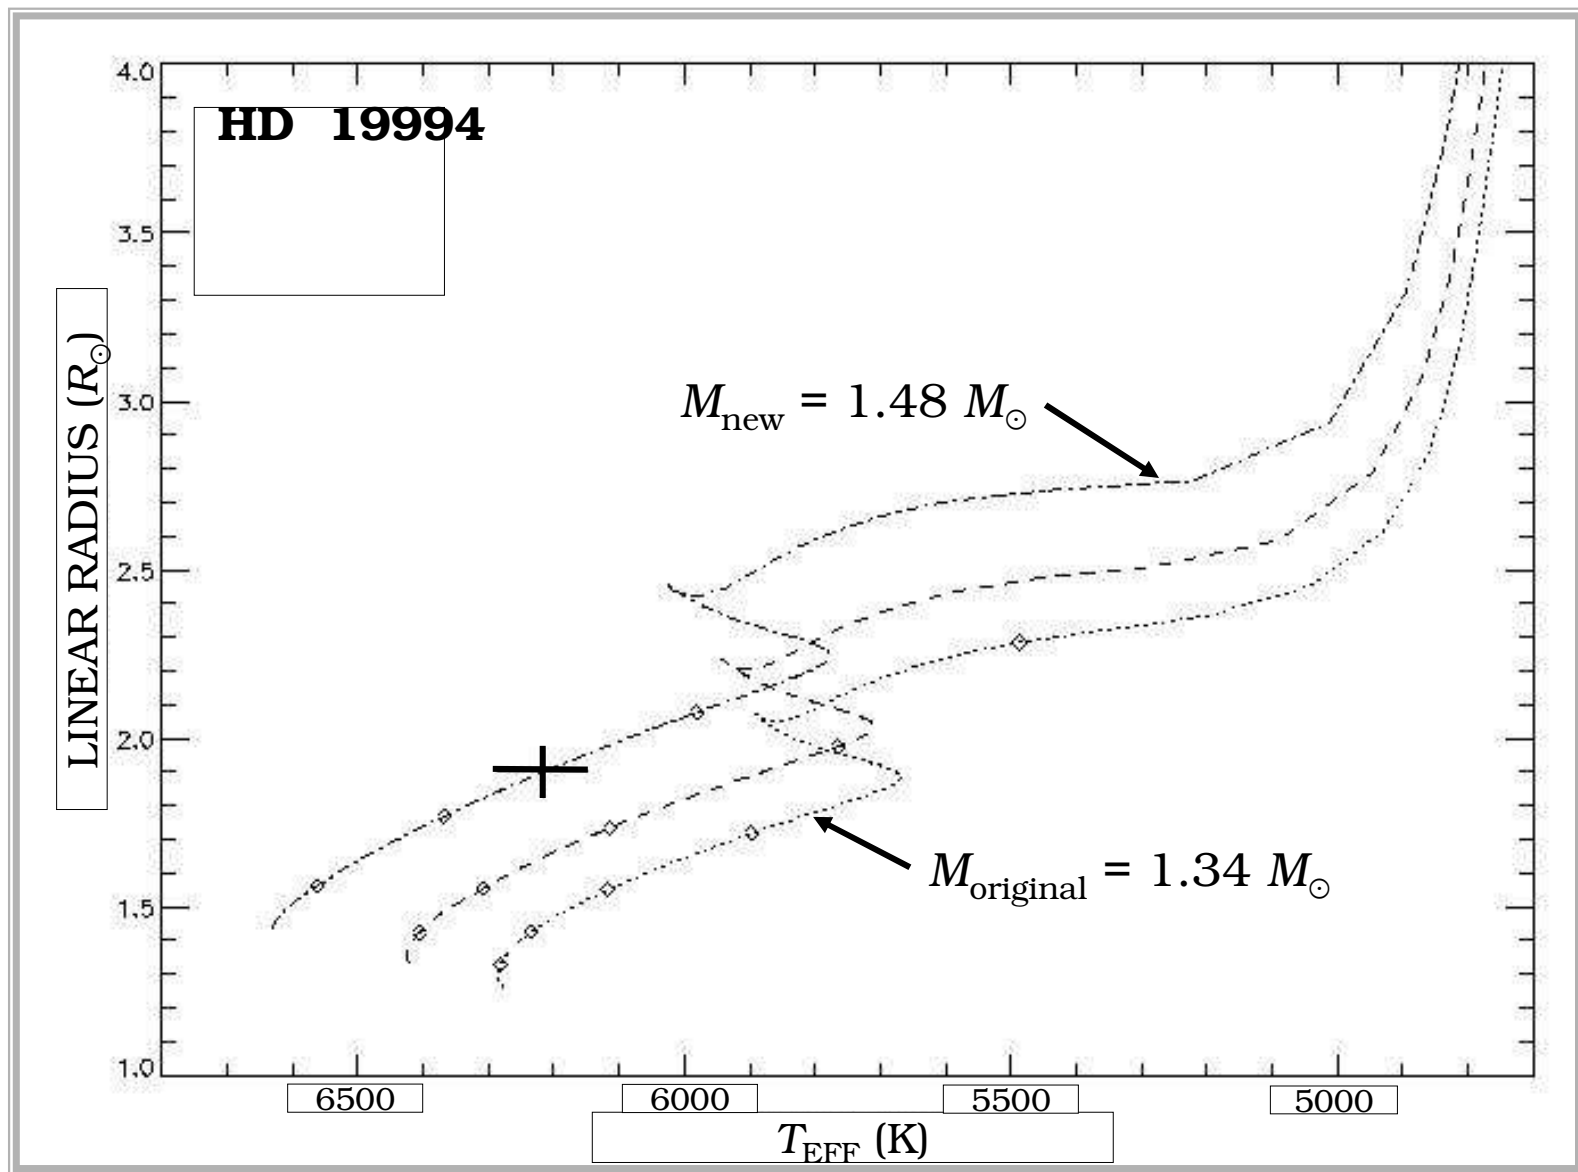

Solution?

Create range of evolutionary tracks
using a stellar model

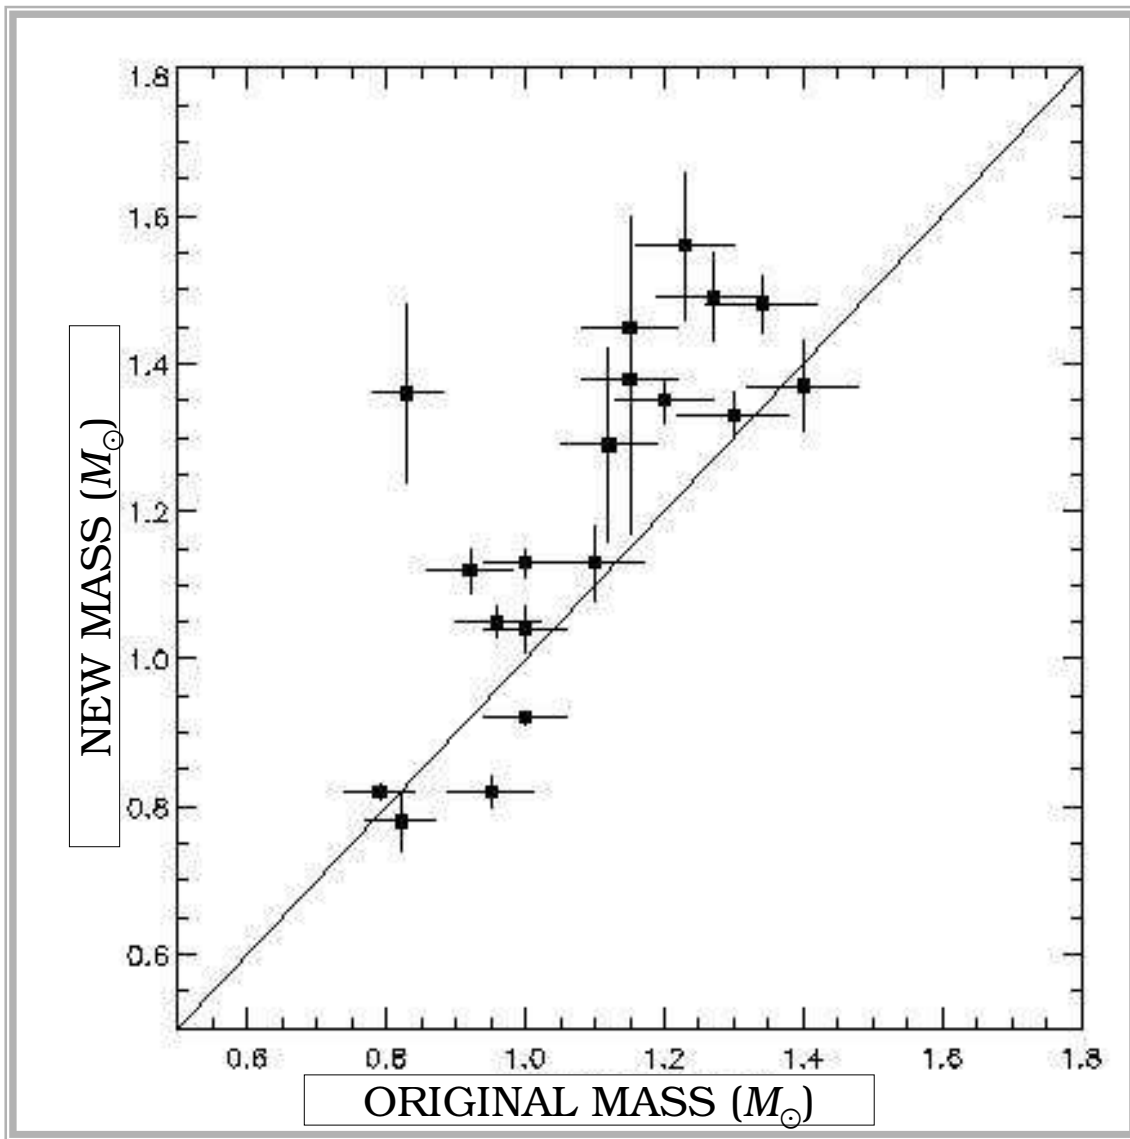

- *Dartmouth Stellar Evolution Simulator*
(<http://stellar.dartmouth.edu/~evolve>)

Match to:

- R_{linear} from interferometry
- T_{eff} from spectroscopy (Santos et al. 2004)

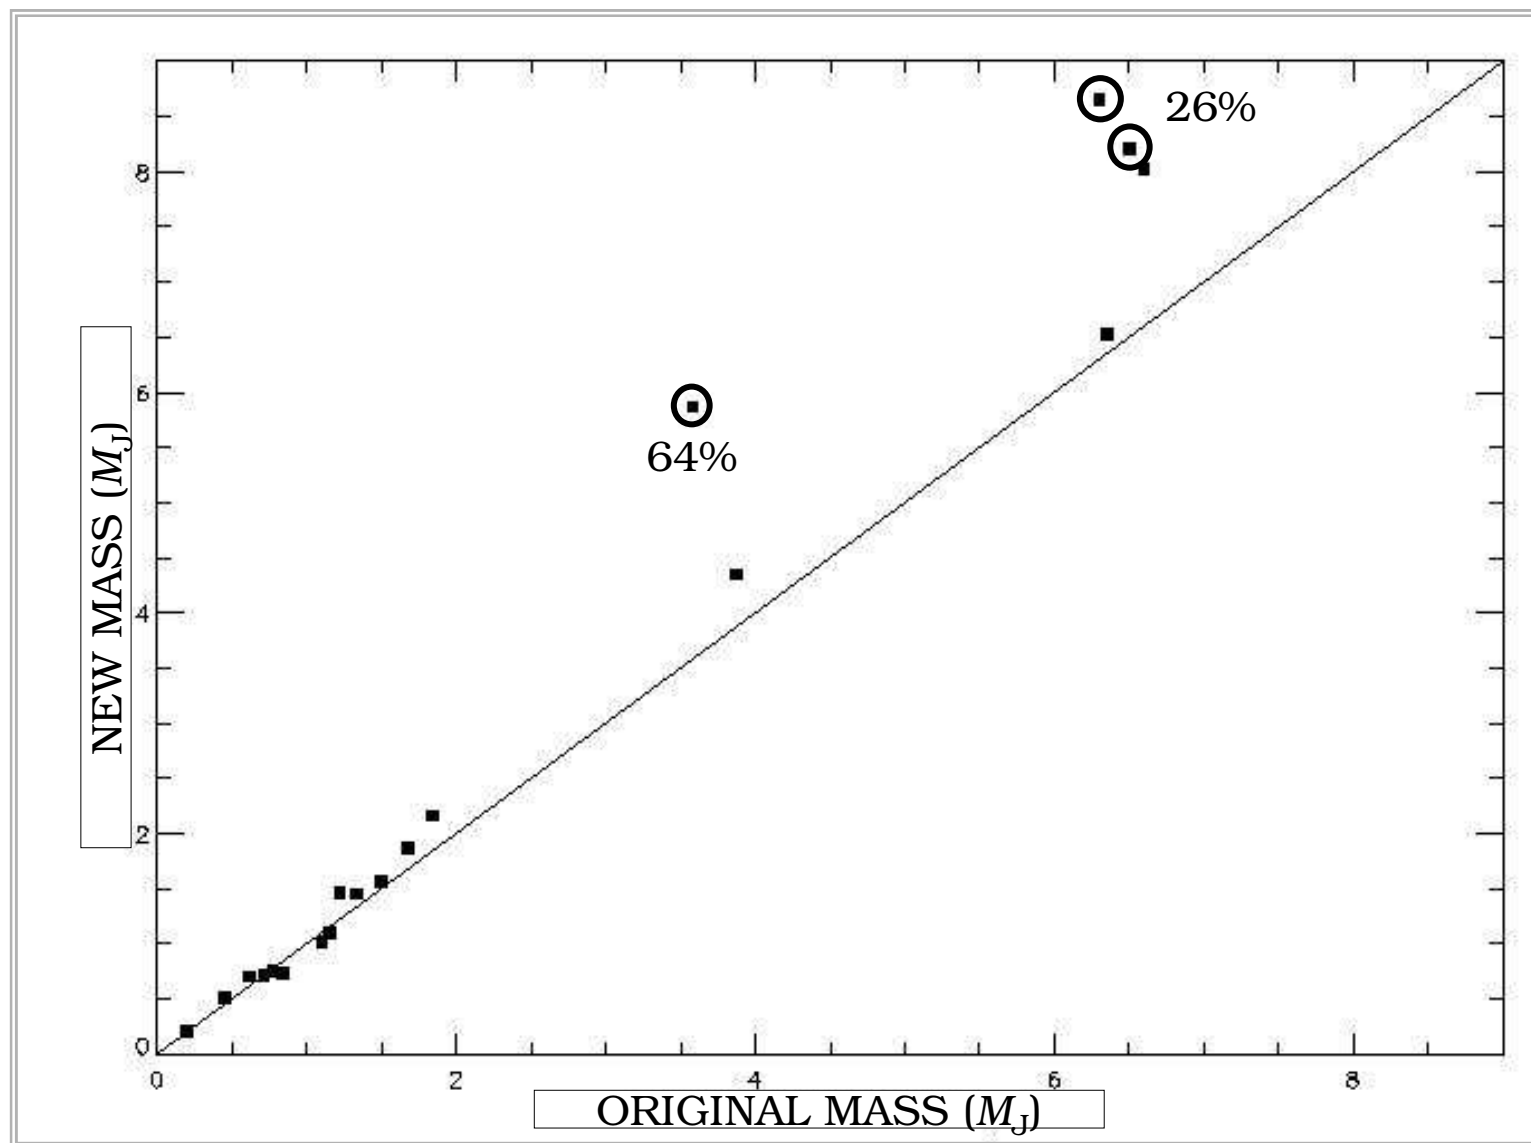

Stars: New vs. Old Mass

- Ave diff = 14%
- New masses changes ages drastically

Planets: New vs. Old Mass

Transiting Planet Diameter

HD 189733

- Discovered by Bouchy et al. (2005):
 - $R_{\star} = 0.76 \pm 0.01 R_{\odot}$
 - Planet-to-star-radii ratio: 0.172 ± 0.003

$$R_{\text{planet}} = 1.26 \pm 0.03 R_{\text{Jup}}$$

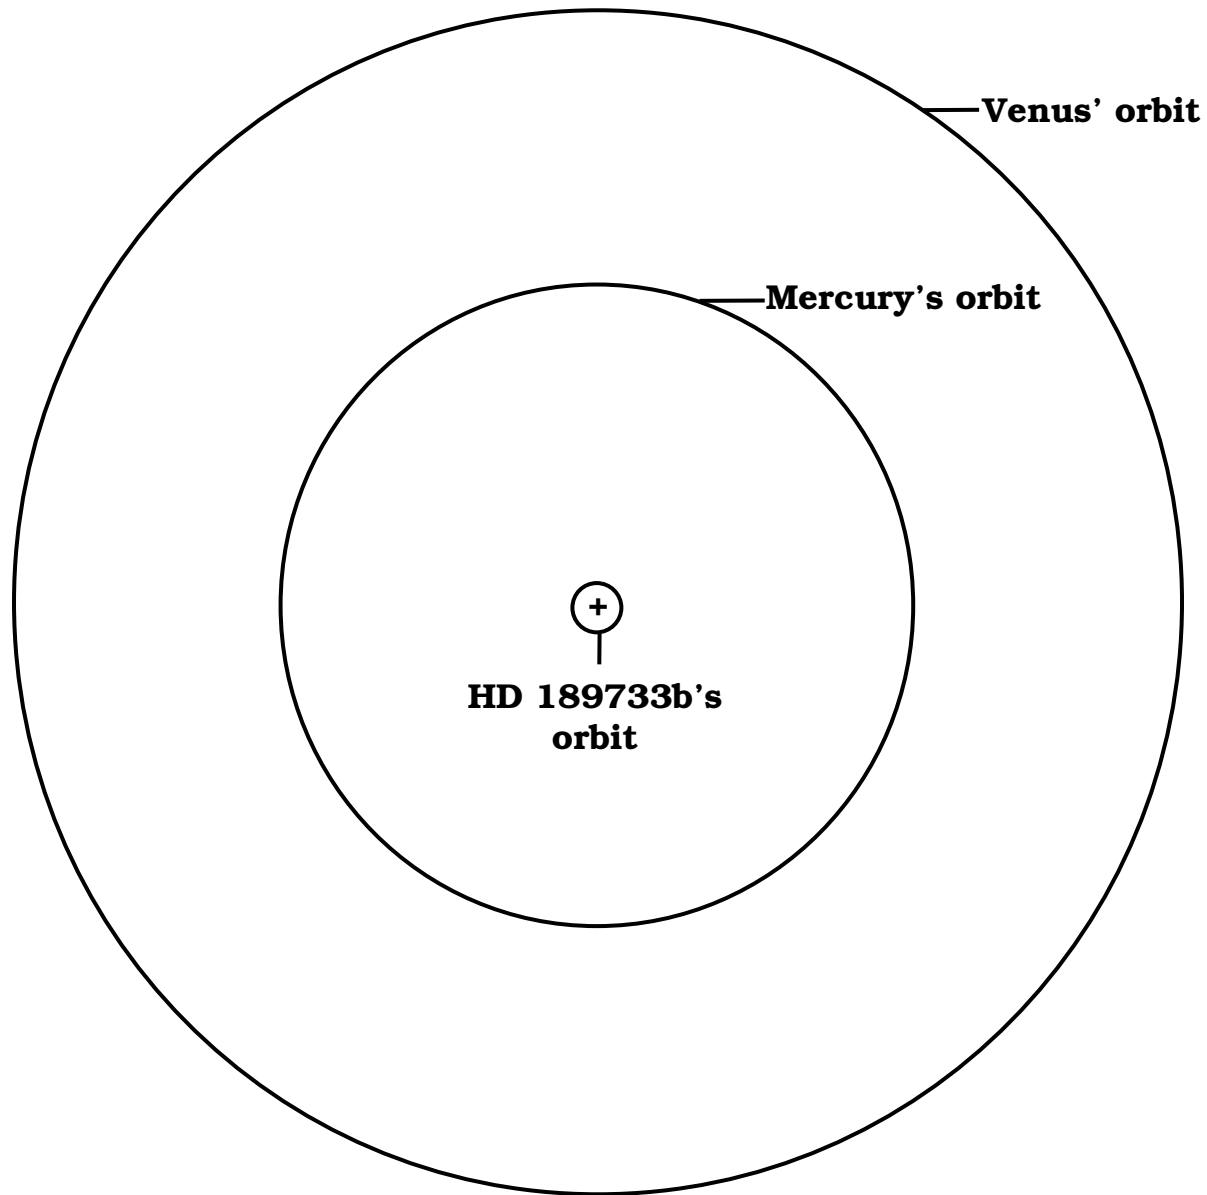

- Bakos et al. (2006) refined planetary parameters:

$$R_{\text{planet}} = 1.154 \pm 0.032 R_{\text{Jup}}$$

CHARA Results

- $\Theta_{\text{LD}} = 0.376 \pm 0.031 \text{ mas}$
- $\pi = 51.9 \pm 0.9 \text{ mas}$
- $R_{\star} = 0.779 \pm 0.066 R_{\odot}$

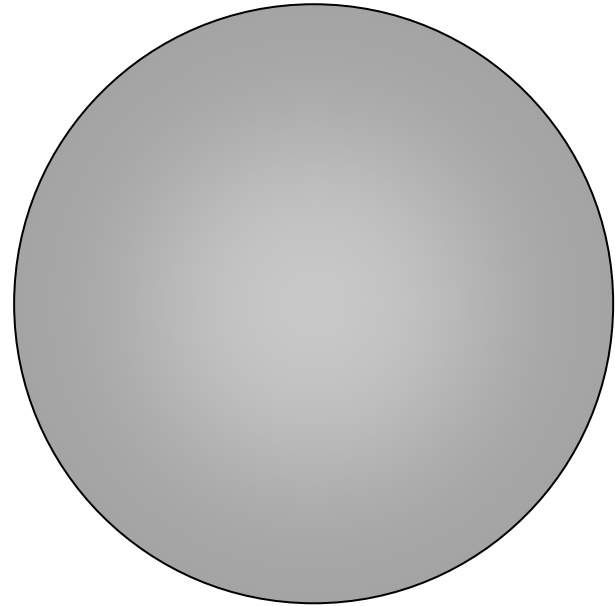

$$R_{\text{planet}} = 1.19 \pm 0.10 R_{\text{Jupiter}}$$
$$\rho = 0.91 \pm 0.23 \text{ g cm}^{-3}$$

Sun

HD 189733

Jupiter

HD 189733b

The Search for Stellar Companions

Basic Premise

In radial velocity observations:

Face-on binary

=

Higher-inclination planet

Interferometry doesn't care about i

Stars vs. Planets

- Orbital element distributions for exoplanets and SBs are statistically identical (Stepinski & Black 2001)
- Models of 8 exoplanets as binary systems match observations (Imbert & Prévot 1998)
 - 4-5% probability

Unknown Inclinations

- Probability of face-on orbit too low to fuss about
 - $P(i): i < 45^\circ = 30\%$ vs. $45^\circ < i < 90^\circ = 70\%$
 - High inclination \rightarrow planetary masses

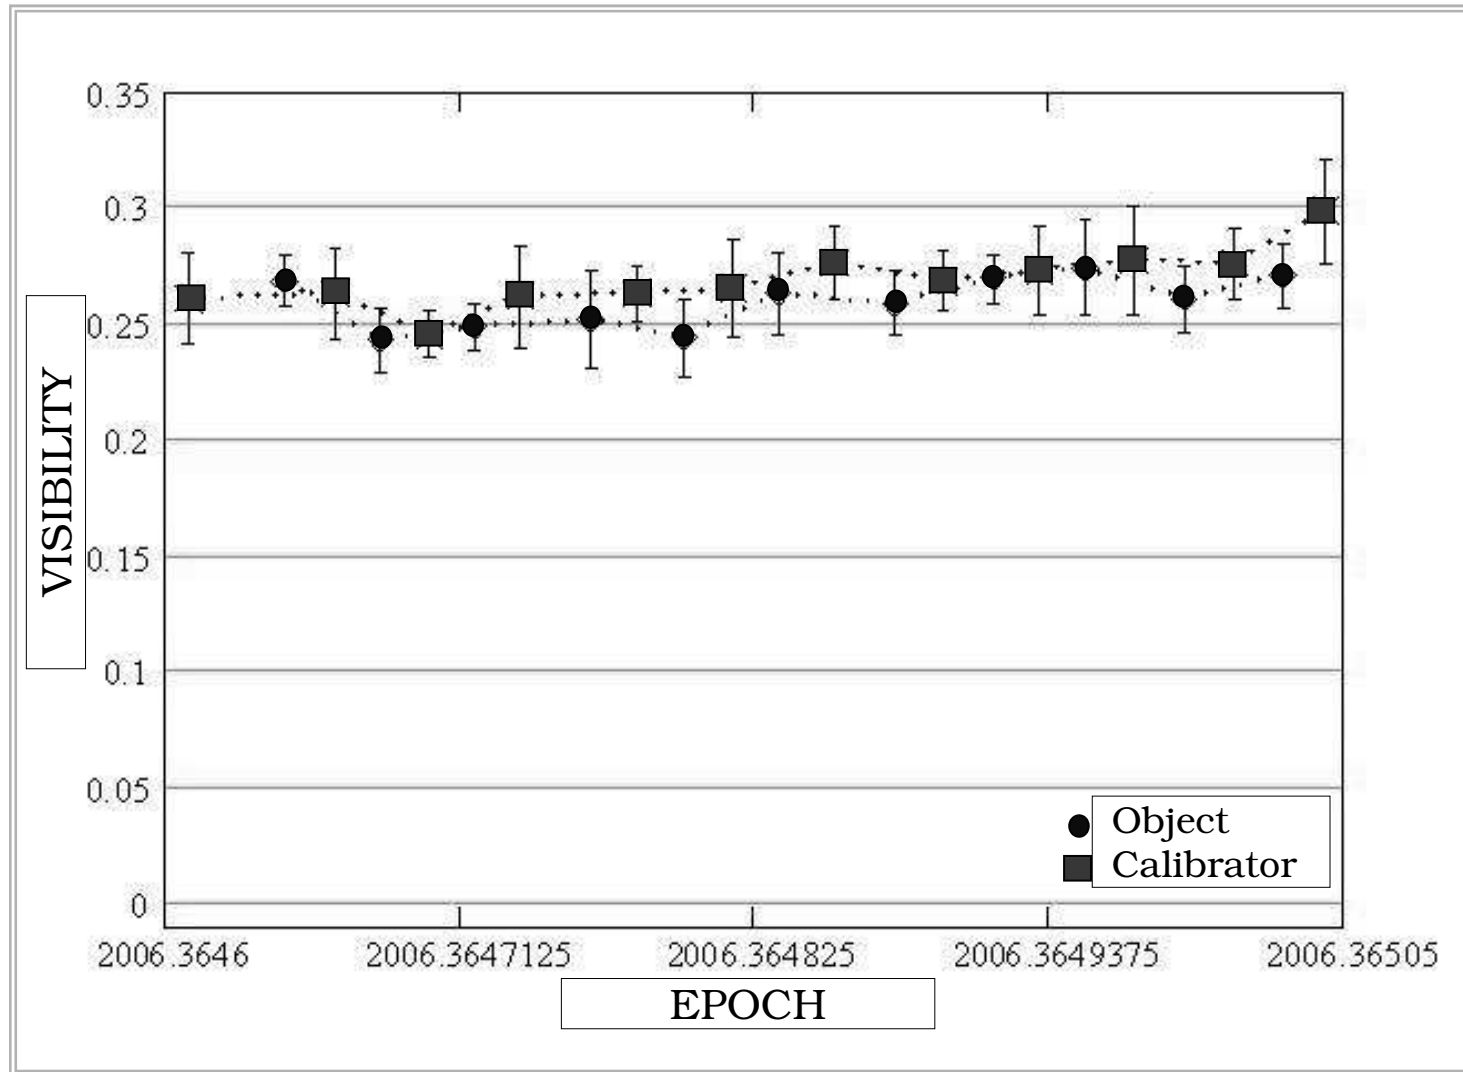

...still...

- In a large enough sample, expect to find a few binary systems

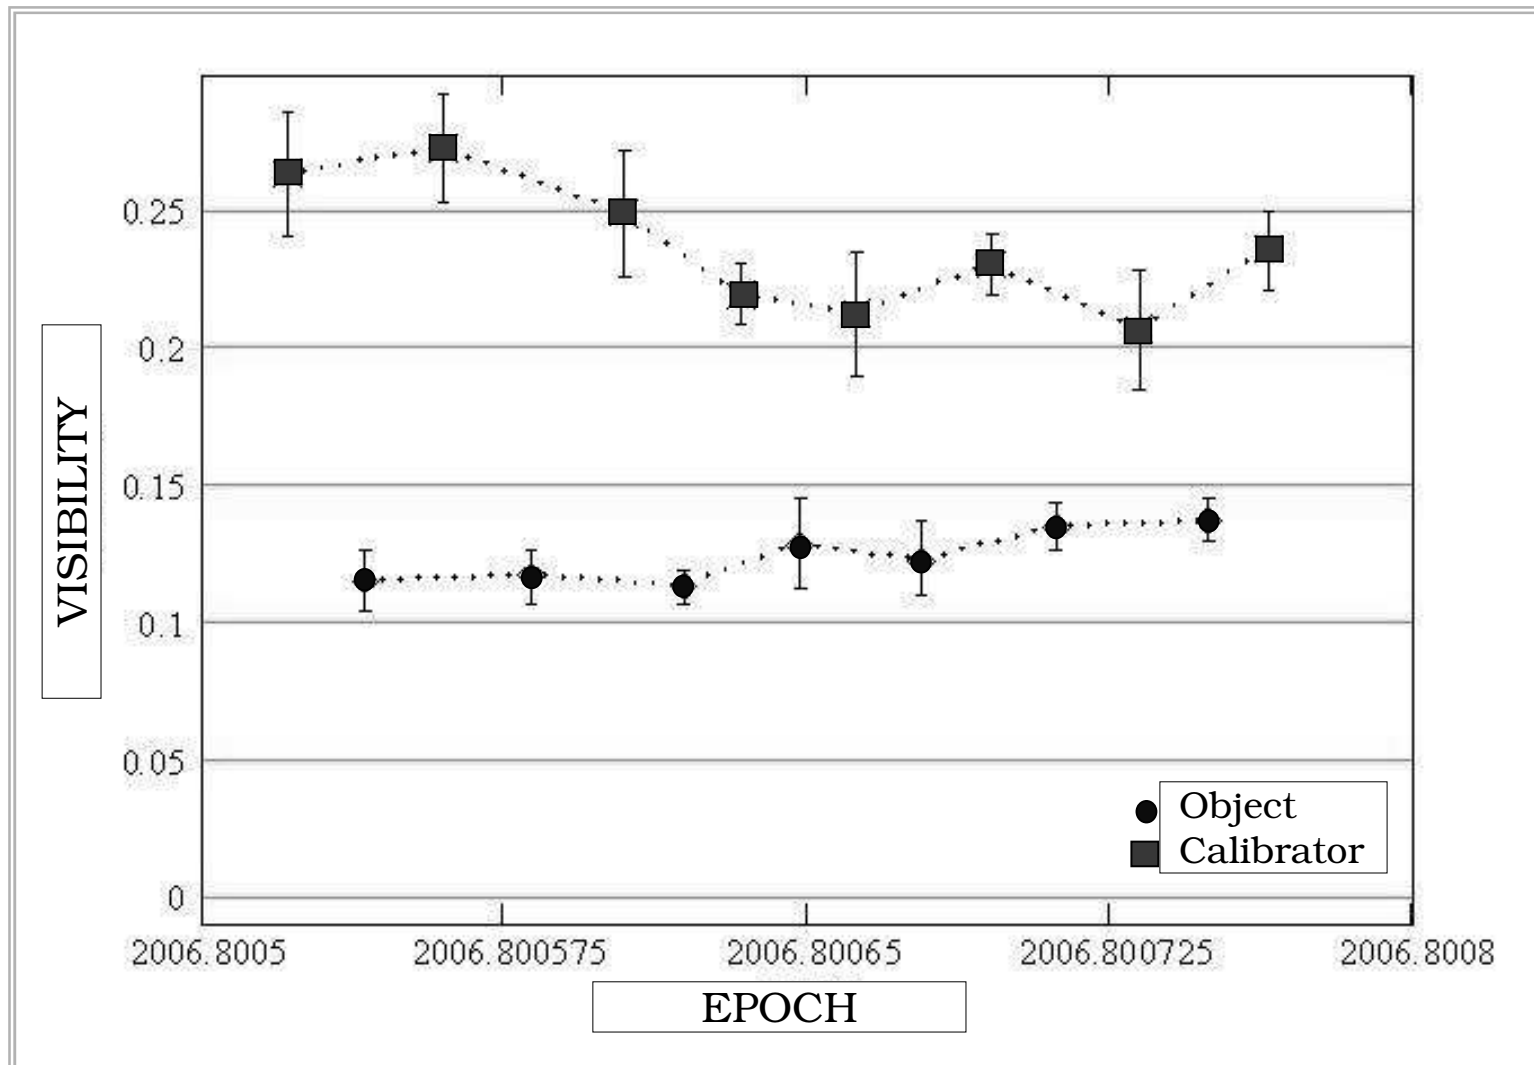

Methods

1. Compare visibility trends between target and calibrator
2. Inspect residuals to visibility curve fit
3. Look for separated fringe packets (SFPs)

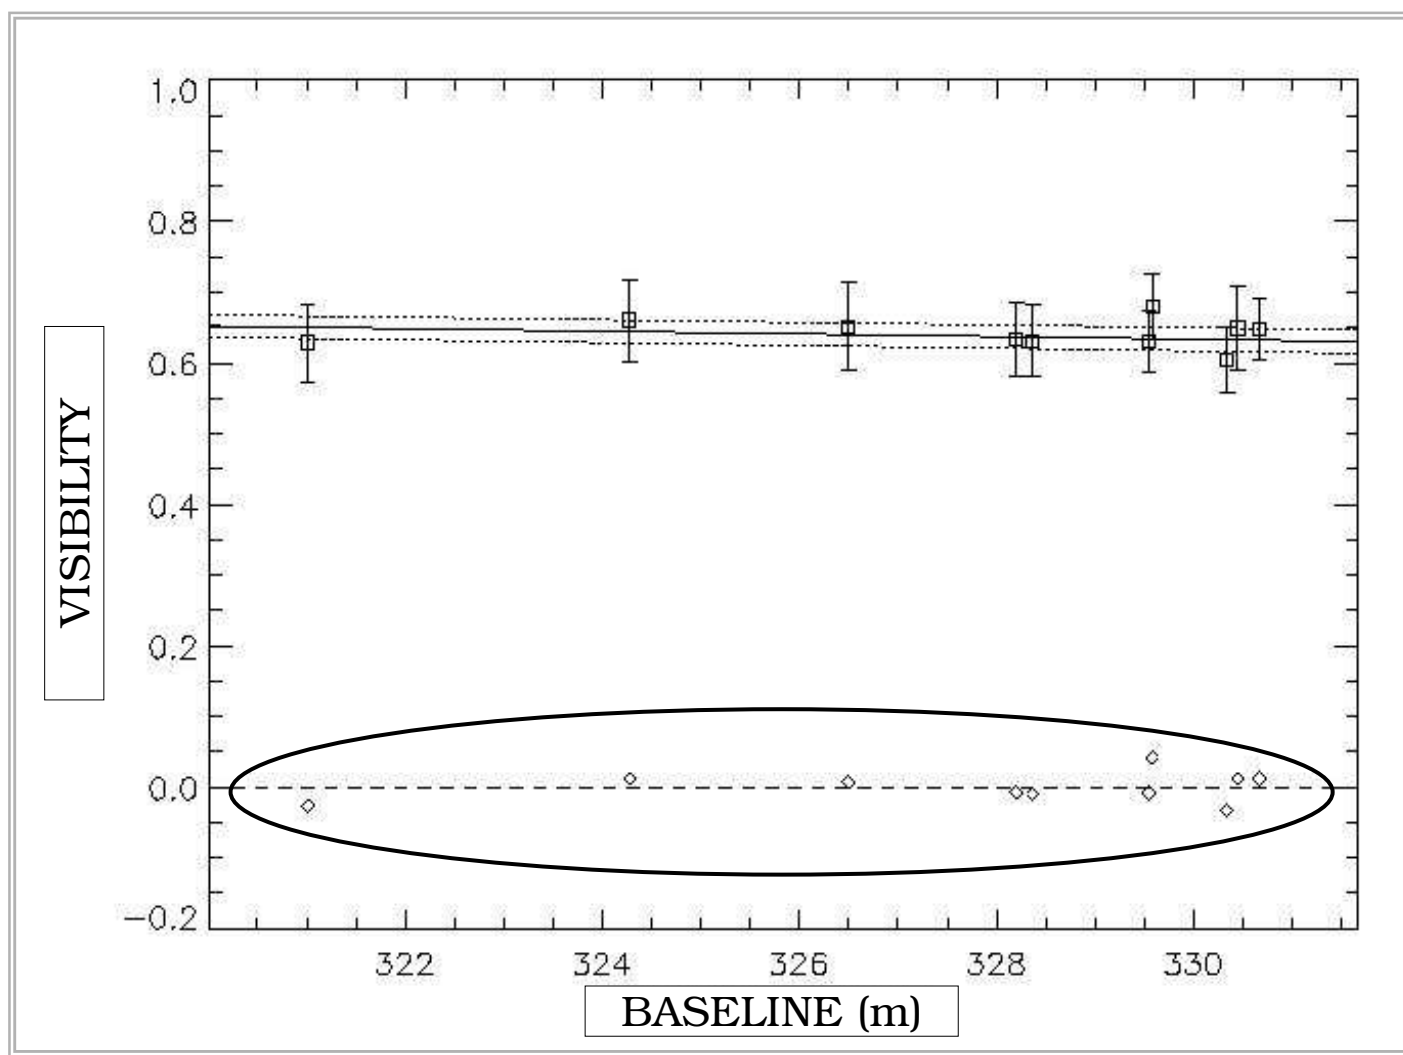

1. Normal Tracking

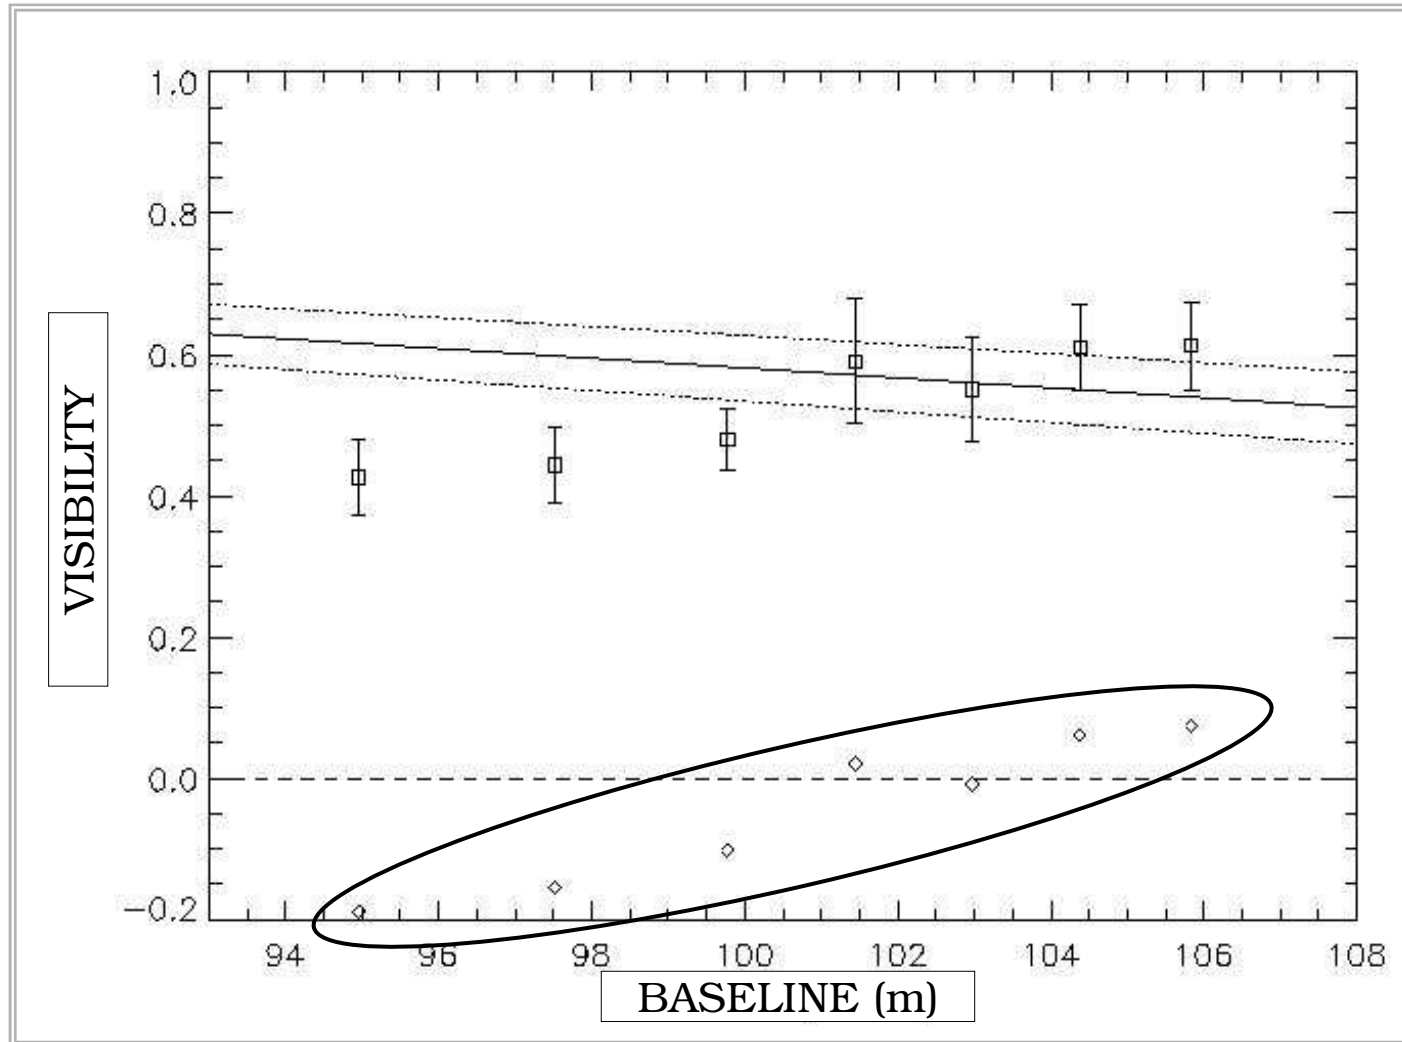

1. Unusual Tracking

2. Single Star Residuals

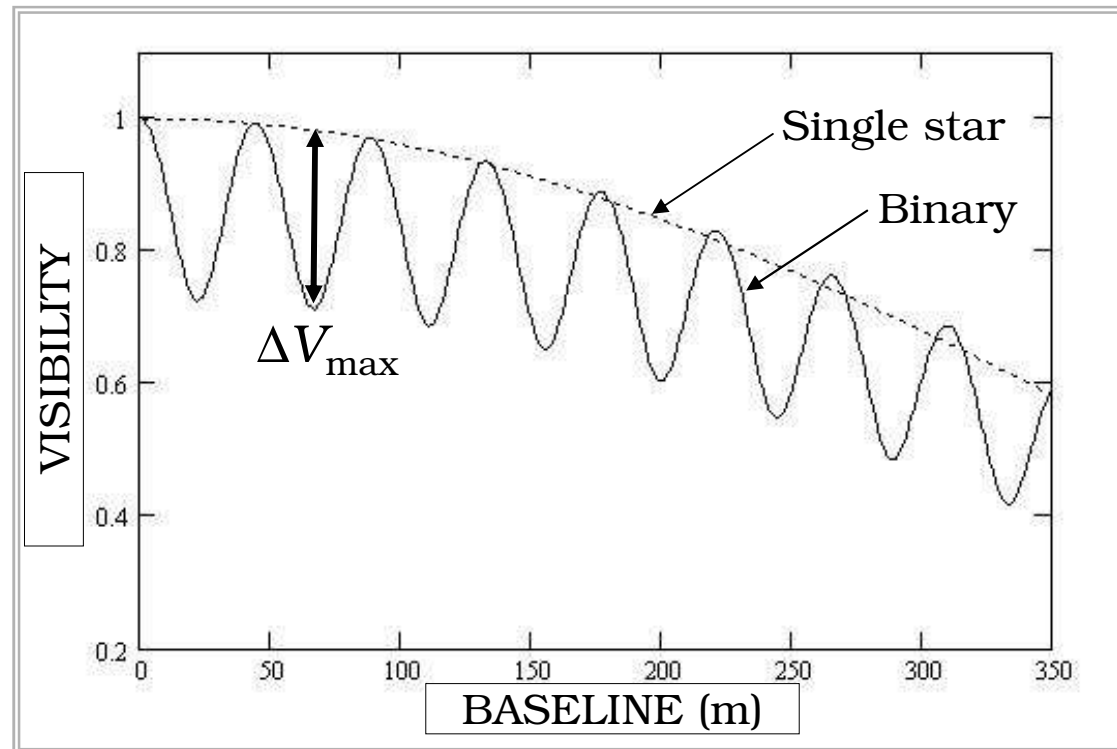

2. Unusual Residuals

2. Single vs. Binary

- Visibility curve for a binary with a given secondary type was created
 - G5 V
 - K0 V
 - K5 V
 - M0 V
 - M5 V

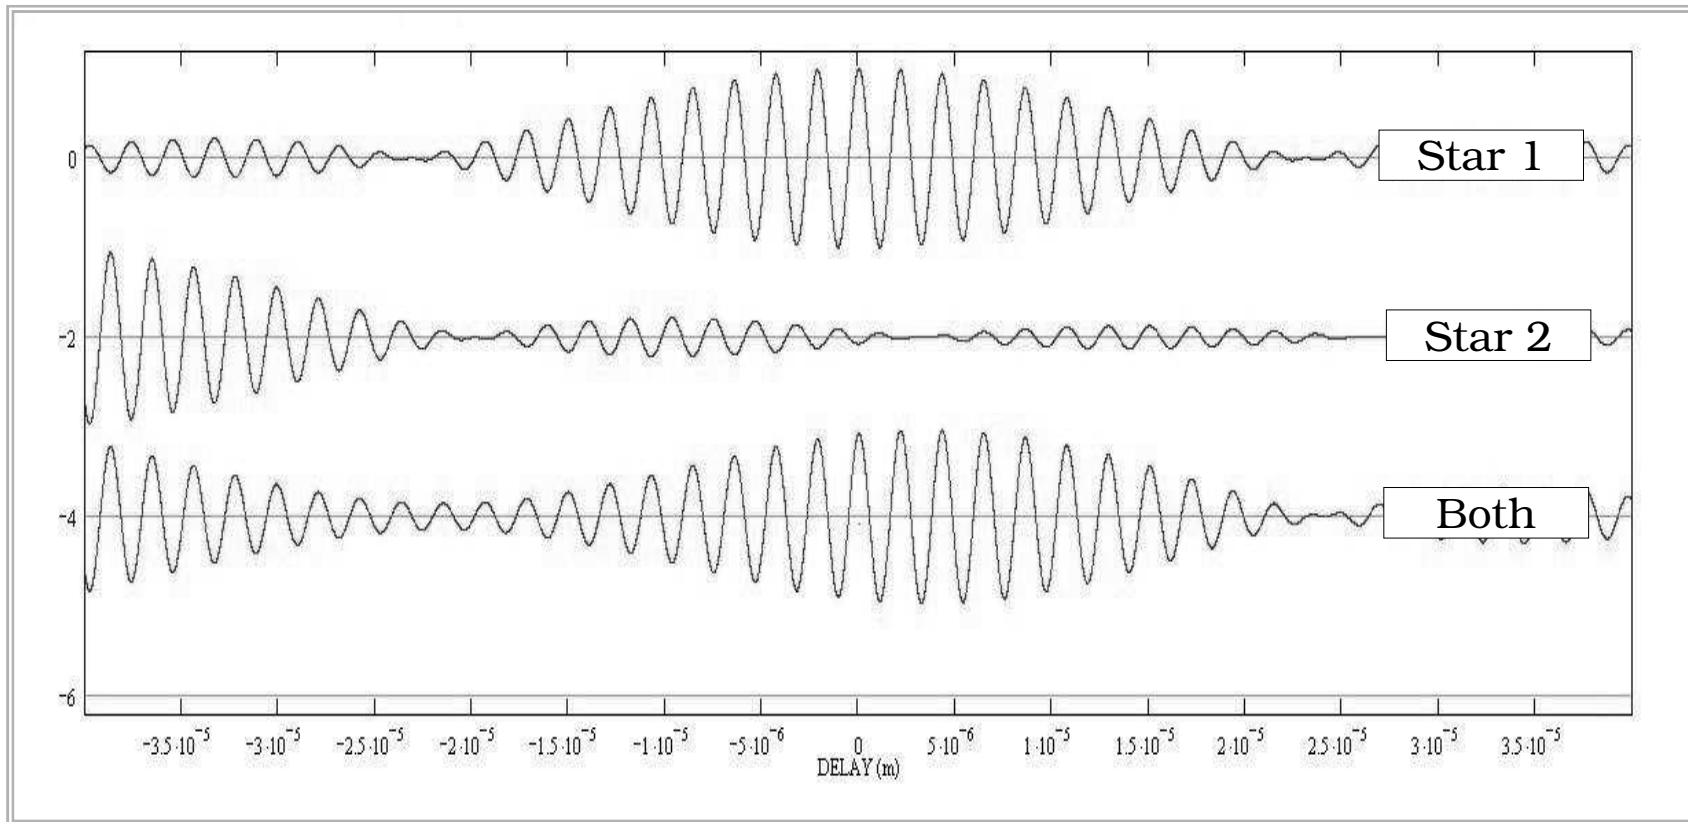

2. Example

σ_{resid}	ΔV_{max} G5 V	ΔV_{max} K0 V	ΔV_{max} K5 V	ΔV_{max} M0 V	ΔV_{max} M5 V
0.100	0.325	0.250	0.210	0.190	0.165
Observed	Theoretical				

- If $\Delta V_{\text{max}} \geq 2\sigma_{\text{resid}}$, that secondary spectral type could be ruled out
- G5, K0, K5 V ruled out; M0, M5 V still possibilities

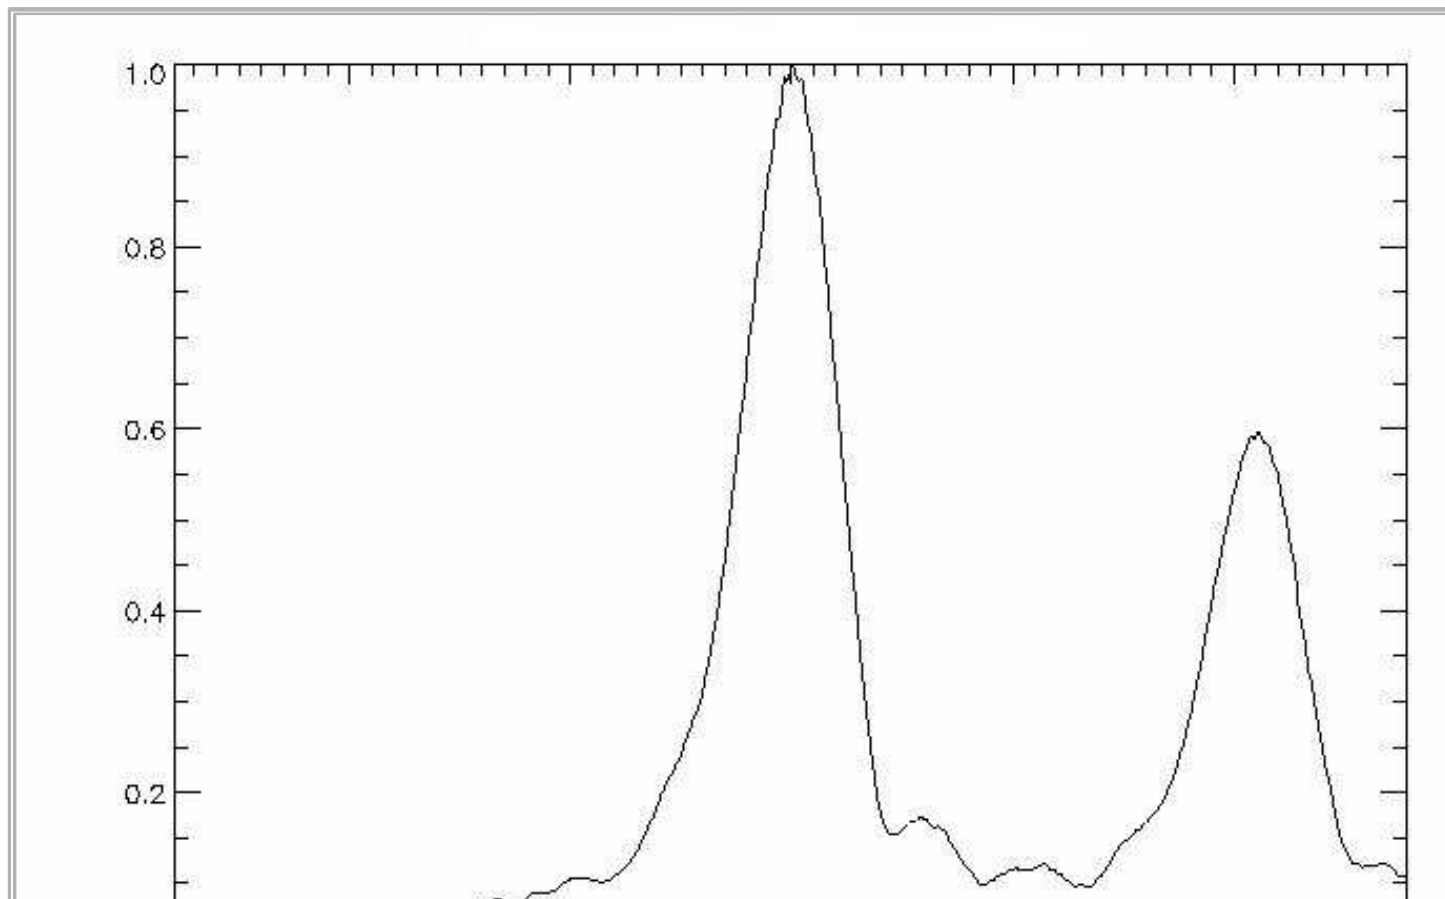

3. Separated Fringe Packets

3. Shift and Add Method

- Find each fringe packet in each of the ~200 scans
- Fit fringe envelope
- Shift each fringe so peak is in the center
- Add fringe amplitudes together
- Result: fringe envelope plot

3. Single vs. Double

No definitive stellar companions found

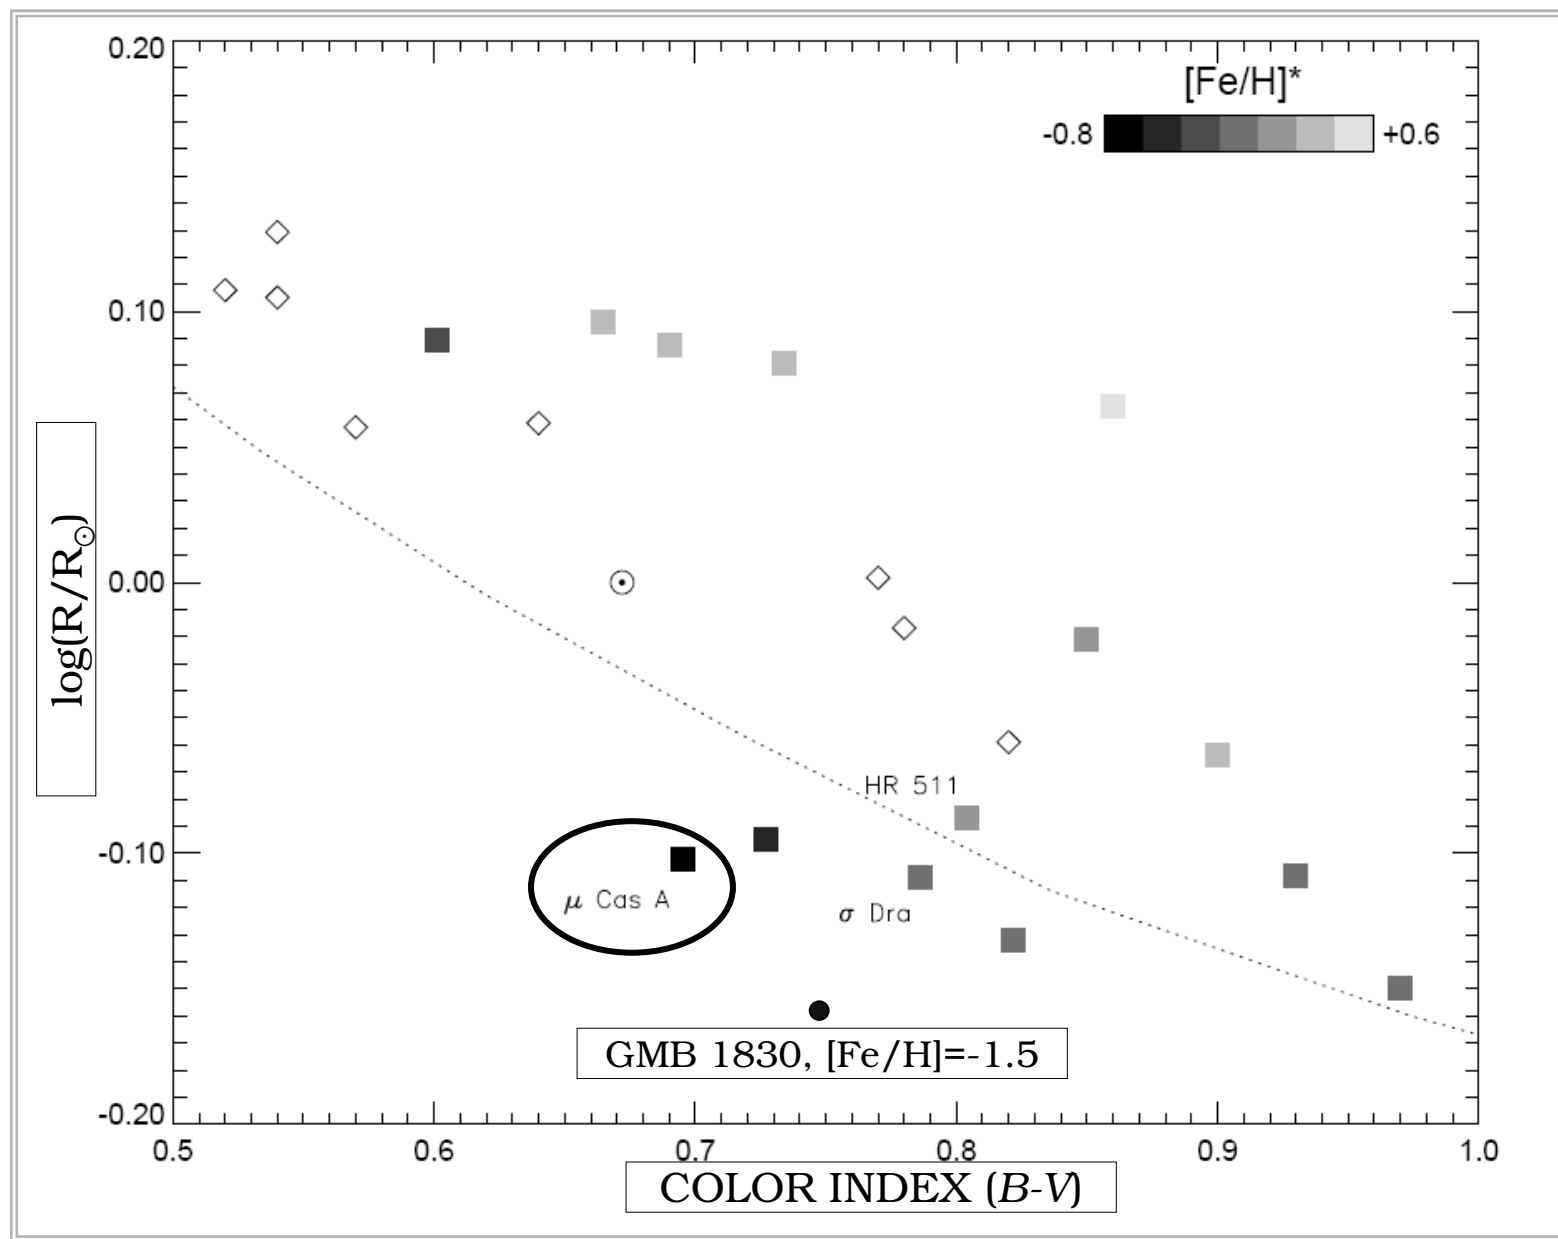

Recent Results: Measuring μ Cas A

μ Cas A

- G5 subdwarf
- Halo population star
- Metal poor
- Higher-metallicity comparison stars:
 - σ Dra, K0 V
 - HR 511, K0 V

Results

- $\theta_{\text{LD}} = 0.973 \pm 0.009 \text{ mas}$
- $R = 0.791 \pm 0.008 R_{\odot}$
- $\theta_{\text{LD}}, F_{\text{BOL}} \rightarrow T_{\text{EFF}} = 5297 \pm 32 \text{ K}$
- $L = 0.442 \pm 0.04 L_{\odot}$
